HAROLD L. ICKES, Secretary

BUREAU OF MINES

JOHN W. FINCH, Director

MINERALS YEARBOOK

1937

Compiled under the supervision of

H. H. HUGHES

Economics and Statistics Branch

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON : 1937

FOREWORD

The activities of the Bureau of Mines fall broadly into three major categories, which complement one another and together constitute a comprehensive and logical program of Government aid in the conservation and orderly development of the national mineral resources. Briefly stated, these activities are grouped as follows: (1) Health and safety work—the improvement of health conditions and the prevention of mine accidents—thus contributing not only to the preservation of life but also to the elimination of the human suffering and economic waste caused by needless accidents; (2) technologic investigations concerning methods used in the mining, preparation, treatment, and utilization of mineral substances, to assist in the more efficient production of minerals and thus promote the conservation of natural resources through the elimination of waste; (3) the compilation and dissemination of basic statistics of the mining industries and the study of economic trends, including all of the phases through which the products of the mines pass before entering into their final uses, thus contributing to the knowledge necessary for the systematic production and conservation of irreplaceable national resources.

Within the last-named group of activities lies one of the most important duties with which the Bureau of Mines has been charged by Congress—that of presenting to the public annually an economic and statistical review of the mineral industries of the United States and the uses to which our mineral wealth is put. The publication of this annual survey of economic developments in the various branches of the mining industry is one of the functions assigned to the Economics and Statistics Branch of the Bureau. The first report in the series of publications presenting the statistics of the mining industry was made under the auspices of the Treasury Department, for the year 1866. The collection of mineral statistics was assigned to the United States Geological Survey upon its establishment in 1879, and was placed on a permanent basis by Congress in 1882. The responsibility for this work was transferred to the Bureau of Mines in 1925. The present *Minerals Yearbook* represents a service of more than 70 years standing and marks the fifty-seventh year of a continuous annual record of economic developments in the mineral industry.

In the 1937 volume have been included the fundamental statistics formerly carried in the statistical appendix. Publication of the appendixes has been discontinued, effecting a considerable saving in cost and an improvement in service in that all essential information is now combined in a single complete volume.

JOHN W. FINCH, *Director.*

CONTENTS

	Page
Foreword, by John W. Finch.....	III
Introduction, by H. H. Hughes.....	XI
Part I. Survey of the mineral industries:	
1. Review of the mineral industry, by Richard J. Lund.....	1
2. Progress in mine mechanization, by O. E. Kiessling, F. G. Tryon, L. N. Plein, and F. E. Berquist.....	29
3. Statistical summary of mineral production, by M. B. Clark.....	53
4. World production of minerals and economic aspects of interna- tional mineral policies, by J. S. McGrath.....	99
Part II. Metals:	
5. Gold and silver, by Charles W. Henderson and J. P. Dunlop.....	111
6. Copper, by J. W. Furness and H. M. Meyer.....	141
7. Lead, by Elmer W. Pehrson and H. M. Meyer.....	171
8. Zinc, by Elmer W. Pehrson.....	191
9. Lead and zinc pigments and zinc salts, by Elmer W. Pehrson and H. M. Meyer.....	211
10. Gold, silver, copper, and lead in Alaska, by Charles W. Henderson..	225
11. Gold, silver, copper, lead, and zinc in Arizona, by C. N. Gerry and Paul Luff.....	233
12. Gold, silver, copper, lead, and zinc in California, by Charles White Merrill and H. M. Gaylord.....	251
13. Gold, silver, copper, lead, and zinc in Colorado, by Charles W. Henderson and A. J. Martin.....	299
14. Gold, silver, copper, lead, and zinc in the Eastern and Central States, by J. P. Dunlop and H. M. Meyer.....	343
15. Gold, silver, copper, lead, and zinc in Idaho, by Paul Luff.....	367
16. Gold, silver, copper, lead, and zinc in Montana, by T. H. Miller.....	405
17. Gold, silver, copper, lead, and zinc in Nevada, by Charles White Merrill and H. M. Gaylord.....	429
18. Gold, silver, copper, lead, and zinc in New Mexico, by Charles W. Henderson and A. J. Martin.....	457
19. Gold, silver, copper, lead, and zinc in Oregon, by Charles White Merrill and H. M. Gaylord.....	477
20. Gold, silver, copper, and lead in South Dakota, by Charles W. Henderson and A. J. Martin.....	499
21. Gold, silver, copper, lead, and zinc in Texas, by Charles W. Hen- derson and A. J. Martin.....	507
22. Gold, silver, copper, lead, and zinc in Utah, by C. N. Gerry and T. H. Miller.....	511
23. Gold, silver, copper, lead, and zinc in Washington, by C. N. Gerry and T. H. Miller.....	537
24. Gold, silver, copper, and lead in Wyoming, by Charles W. Hen- derson and A. J. Martin.....	555
25. Secondary metals, by J. P. Dunlop.....	559
26. Iron ore, pig iron, ferro-alloys, and steel, by Robert H. Ridgway and H. W. Davis.....	573
27. Manganese and manganiferous ores, by Robert H. Ridgway and H. W. Davis.....	617
28. Chromite, by Robert H. Ridgway.....	633
29. Nickel and cobalt, by Richard J. Lund.....	641
30. Molybdenum, tungsten, and vanadium, by Richard J. Lund.....	651
31. Bauxite and aluminum, by Herbert A. Franke and C. T. Herring..	665
32. Mercury, by H. M. Meyer.....	683
33. Tin, by R. B. Miller.....	697
34. Arsenic and bismuth, by Herbert A. Franke.....	711

Part II. Metals—Continued.	Page
35. Magnesium, by Herbert A. Franke.....	721
36. Antimony and cadmium, by Elmer W. Pehrson and John B. Umhau.....	731
37. Platinum and allied metals, by H. W. Davis.....	747
38. Minor metals, by Paul M. Tyler.....	759
Part III. Nonmetals:	
39. Coal:	
Part 1. Bituminous coal, by F. G. Tryon, L. Mann, and W. H. Young.....	787
Part 2. Pennsylvania anthracite, by F. G. Tryon, H. L. Bennit, and J. R. Bradley.....	867
40. Coke and byproducts, by W. H. Young, H. L. Bennit, and M. Otero.....	891
41. Recent developments in coal preparation and utilization, by Arno C. Fieldner.....	938
42. Fuel briquets, by L. N. Plein and J. B. Clark.....	955
43. Peat, by F. M. Shore.....	969
44. Crude petroleum and petroleum products, by A. G. White, G. R. Hopkins, and H. A. Breakey.....	973
45. Natural gas, by F. S. Lott and G. R. Hopkins.....	1055
46. Natural gasoline, by G. R. Hopkins.....	1091
47. Carbon black, by G. R. Hopkins and H. Backus.....	1109
48. Helium, by H. S. Kennedy and C. W. Seibel.....	1119
49. Asphalt and related bitumens, by A. H. Redfield.....	1123
50. Cement, by Oliver Bowles and B. W. Bagley.....	1137
51. Stone, by Oliver Bowles and A. T. Coons.....	1165
52. Slate, by Oliver Bowles and M. Schauble.....	1201
53. Sand and gravel, by H. H. Hughes and M. A. Cornthwaite.....	1211
54. Gypsum, by Carl A. Gnam.....	1227
55. Lime, by Oliver Bowles and A. T. Coons.....	1239
56. Clays: Kaolin (china clay and paper clay), ball clay, fire clay, bentonite, fuller's earth (bleaching clays), and miscellaneous clay, by Paul M. Tyler and R. W. Metcalf.....	1255
57. Magnesite and other magnesium compounds, by Paul M. Tyler and A. E. Davis.....	1271
58. Abrasive materials, by Bertrand L. Johnson and A. E. Davis.....	1283
59. Sulphur and pyrites, by Robert H. Ridgway and A. W. Mitchell.....	1301
60. Phosphate rock, by Bertrand L. Johnson and K. G. Warner.....	1315
61. Talc and ground soapstone, by Carl A. Gnam and M. A. Cornthwaite.....	1329
62. Fluorspar and cryolite, by H. W. Davis.....	1337
63. Feldspar, by R. W. Metcalf.....	1353
64. Asbestos, by Oliver Bowles and M. A. Cornthwaite.....	1363
65. Barite and barium products, by Bertrand L. Johnson and M. A. Cornthwaite.....	1371
66. Potash, by J. H. Hedges.....	1381
67. Mica, by Bertrand L. Johnson and M. A. Cornthwaite.....	1399
68. Salt, bromine, calcium chloride, and iodine, by A. T. Coons and F. E. Harris.....	1413
69. Natural sodium compounds and boron minerals, by A. T. Coons.....	1429
70. Gem stones, by Sydney H. Ball.....	1435
71. Minor nonmetals: Graphite, greensand, kyanite, lithium minerals, mineral wool, monazite, olivine, strontium minerals, and vermiculite, by Paul M. Tyler.....	1441
Part IV. Mine safety:	
72. Employment and accidents in the mineral industries, by W. W. Adams.....	1453
Index, by M. E. Winslow.....	1467

111. Trends in domestic sales, imports, consumption, and average value f. o. b. mines of crude barite, 1921-36.....	1371
112. Crude barite (domestic and imported) used in the manufacture of barium products in the United States, 1927-36, in percent of total consumption.....	1374
113. Ratio of indexes of crude-barite consumption and domestic lithopone sales (1923-25 average=100) to Federal Reserve Board index of industrial production (1923-25 average=100), 1921-36.....	1375
114. World production of crude barite, by countries, 1927-36.....	1376
115. Trends in imports of splittings, and of imports and domestic production of the better grades of sheet mica, 1927-36.....	1400
116. Percentage of ground mica used by consuming industries in the United States, 1927-36.....	1404
117. Index of salt sold or used compared with Federal Reserve Board index of industrial activity, 1919-36.....	1414
118. Quantity and value of natural sodium compounds (other than NaCl) produced in the United States, 1927-36.....	1430
119. Trend of employment at mines and quarries in the United States, 1911-34.....	1454
120. Trend of fatal accidents at mines and quarries in the United States, 1911-34.....	1455

INTRODUCTION

Measured in terms of capital investment, value of products, or number of workers employed, mining ranks last among the four primary industries of the United States. These conventional yardsticks, however, are not altogether accurate indicators of the importance of mining in our national economy. Actually mining is coordinate with manufacturing, agriculture, and transportation because each of these primary industries is critically dependent upon the products of the mines. Manufacturing draws on the minerals both for its machines and for the power to operate them. The products of the mines constitute nearly two-thirds of the revenue freight handled by the railroads and about one-fourth of the ocean-borne traffic. Even agriculture now leans heavily on minerals for its fertilizers and its implements of cultivation and harvesting. Moreover, minerals are necessary to link the farms with the markets. The products of the mines, in fact, form the material basis for modern industry.

With minerals playing so prominent a role in our economic environment, the need for precise information concerning each of the separate branches of the mining industry is at once apparent. Producers and consumers must have the complete facts on production, stocks, consumption, prices, distribution, employment, and other pertinent questions as a basis for intelligent action. The empirical method of guessing will no longer suffice, nor are the essential facts concerning an isolated branch of mining enough. In such a complex economy it is important to know not only how the various branches are interrelated but also how the separate segments interlock into our industrial system as a whole.

To meet the demands for factual data concerning the mineral industries, various agencies of the Federal Government have published periodic surveys for nearly three-quarters of a century. Prior to 1880, the task was assigned to the Treasury Department. During this period the reports were generally on a biennial basis and were primarily concerned with regional mining descriptions. In 1880, the work was transferred to the newly created United States Geological Survey, where it was established on a permanent annual basis. Finally, in 1925 the mineral statistics work was again transferred—this time to the United States Bureau of Mines. These various shifts have resulted in administrative changes, but have not affected the publication of the separate chapters or impaired the continuity of the annual reports.

Although the annual series has remained unbroken since 1880 (this report marks the fifty-seventh annual record), the form and treatment have repeatedly been modified to meet the exigencies of the times. The last major change was in 1933, when the title of the series was changed from *Mineral Resources of the United States* to *Minerals Yearbook* and,

in response to the demand for more timely service, the date of publication was advanced by approximately a year. Another change is introduced with this volume. Since 1933 it has been the practice of the Bureau to issue the complete report as promptly as possible and, for the few industries for which final statistics were not available, to release supplemental chapters giving the detailed figures. These chapters were later assembled and published in bound form as the Statistical Appendix to the Yearbook. As final figures for virtually all branches of the mineral industry except coal, petroleum, stone, and a few others are completed in time for publication in the Yearbook, the practice of issuing the supplementary appendix chapters has been discontinued. For the few industries for which final statistics are not available, the revised and detailed information will be summarized in mimeographed releases and included in the Yearbook for the succeeding year. This change will result in considerable saving and, in addition, will have the advantage of bringing together in a single reference volume all the essential information concerning the mining industry.

Like its predecessors, Minerals Yearbook, 1937, has been made possible by the cooperation of those interested in mining. It is a pleasure to acknowledge the generous support of the thousands of individual producers, distributors, and consumers and of the many public officials and agencies that have supplied information. In addition, the Bureau is indebted to a large number of trade associations for liberal contributions and advice.¹

Maintenance of continuity of data and uniformity of statistical presentation throughout the Minerals Yearbook volumes has been effected largely through the work of M. B. Clark.

Special thanks are due H. O. Rogers, economic analyst of the Bureau of Labor Statistics, who was loaned to the Bureau of Mines to assist in the final stages of preparation of the manuscript. E. T. Shuey assisted in reviewing and checking statistical chapters. Max Abel supervised the preparation of graphic material, and C. W. Justice helped in many phases of the Yearbook program. M. E. Winslow supplied helpful suggestions for improvement of the individual contributions and, in collaboration with A. B. Brown and E. C. Reid, was responsible for the editing of the entire manuscript.

H. H. HUGHES.

Accompanying the vigorous, sustained, and well-diversified business improvement during 1936, the industries engaged in mineral extraction in the United States continued to make marked recoveries from the curtailed activities of depression years. Taking the average for 1923-25 as 100, the Federal Reserve index of total industrial production rose from 90 in 1935 to 105 in 1936, a gain of about 17 percent. On the same basis, the index of mineral production rose about 14 percent—from 91 in 1935 to 104 in 1936. These gains are all the more striking when account is taken of the fact that extraordinarily severe winter weather and disastrous floods caused a mild recession in industrial activity during the first 3 months of 1936. So vigorous was the rise after March that the index of total production stood at 121 for December, which was the highest since October 1929.

The major factor contributing to this gain, and of vital importance in reviving the mineral industries, was the abrupt rise in production of durable goods. (See fig. 1.) The release of pent-up demand was in full swing for such articles as automobiles, busses, trucks, railway passenger and freight cars and rails, locomotives, electric refrigerators, air-conditioning equipment, heavy and light machinery of all types, radios, and dozens of other commodities of the durable type, and many industries in this group established new production records in 1936. Replacement of worn-out and obsolete equipment of all kinds by industry and by private individuals, long postponed during the depression years, became a major force during the year. Destruction of hundreds of millions of dollars' in property of various kinds by the widespread floods early in 1936 doubtless contributed to this movement.

Typifying the result of this revival of demand for durable goods was the iron and steel industry, which steadily increased output of ingot steel from about 51 percent of capacity in January 1936 to 78 percent in December; the average for the year was about 68 percent compared with 49 percent in 1935. Not only were increased operations in this

industry illustrative of the effects of such long-dormant needs to replace equipment, but, by its phenomenal expansion in finishing capacity through construction of six huge continuous sheet and wide strip mills in 1936,¹ the steel industry also typified the replacement and modernizing movement itself. Apparently much remains to be done in revivifying such divisions of the industry as coking, blast-furnace, and soaking-pit capacities.²

FIGURE 1.—Production of durable manufactures compared with nondurable manufactures, in comparable units and adjusted for seasonal variation, 1929-36. Data compiled by Federal Reserve Board from figures included in its index of manufactures.

Increased earnings by the railroads effected by greater freight and passenger traffic finally permitted expenditure of large sums in replacing freight cars, passenger cars, locomotives, and worn rails. Earlier success in meeting airplane and motorbus competition for passenger traffic by speeding up schedules and modernizing equipment resulted in addition of many more deluxe streamlined Diesel or steam units.

The automotive industry continued its upward climb toward peak production levels with an output of 4,616,857 units (3,807,371 passenger cars and 809,486 trucks and busses), in the United States and Canada. The Canadian production is included, since much of it consists of assembly of parts brought in from the United States. The increase over 1935 is all the more impressive; since that year witnessed the introduction of two new yearly models.

REVIEW OF THE MINERAL INDUSTRY

Truck and bus production in the United States reached a new record, as did total registration of motor vehicles.

The important role played by the automotive industry in consumption of important minerals is shown in the following table:

*Relation of various metals and mineral products used by the automotive industry, in manufacturing and repairs, to total consumption in the United States, 1932-36 in percent*¹

	Steel	Copper	Lead	Zinc	Aluminum	Tin	Nickel	Plate glass	Gasoline	Lubricating oils

1936 ²	21	17	35	15	16	13	28	72	80	59

¹ Steel is compared with total production of finished rolled steel, tin with total deliveries, nickel with total sales, and plate glass with total production of polished plate glass in the United States. (Data from Automobile Facts and Figures (annual volumes), Automobile Manufacturers' Association.)

² Preliminary figures.

It should be clearly understood that these data represent percentages used not only in manufacturing new motor vehicles (trucks and busses included), but also in repairs and replacements to old vehicles. Lead going into battery replacements (which in normal times is largely a revolving supply, since old battery plates are remelted and re-formed into new ones with little loss) is the outstanding case of repair or replacement usage. The increase in the zinc figures is worthy of note, as it was doubtless brought about by the expanded use of zinc die castings for decorative features and other intricate, unstressed parts. The employment of steel in motor vehicles needs no further explanation, except perhaps notation of the fact that the movement toward all-steel bodies and streamlining has tended to raise the amount of steel used per pound of car weight. It has been estimated³ that about 150 pounds more steel per car was used in 1936 than in 1935. Copper is the chief constituent of the radiator and electrical parts; tin and lead are in the solder in the radiator and in the numerous bearings; aluminum is in pistons, crankcases, and cylinder heads of many models; and nickel is in special alloy steel or iron used in such highly stressed parts as shafts, gears, steering apparatus, and crankshafts, and as an undercoating for chrome-plated equipment.

An infant branch of the automotive industry, progressing by leaps and bounds, is the passenger trailer business. Production totaled about 60,000 units in 1936 compared with 27,500 in 1935; estimates for 1937 production are around 80,000 units. Possible limitations on the future trailer market and other interesting features of the business were discussed by Applegate.⁴

The position of utility corporations, large consumers of fuels and copper, was improved in 1936 by a new record in electricity production. A total of 114 billion kilowatt-hours of electricity was produced compared with 99 billion in 1935 and 97 billion in 1929. The ratio of 64 percent generated by fuel power and 36 by water power in 1936 was almost identical with 1929, but represented a small gain for fuel power

³ Steel, Automobiles: Jan. 4, 1937, p. 260.

⁴ Applegate, La Rue, Trailer Production Shows Phenomenal Growth Typical of "Infant Industries": *Analyst*, Mar. 26, 1937, p. 475.

compared with 1935. Consumption of gas in electricity generation reached a new record figure of 156 billion cubic feet in 1936. The steady trend toward better conversion efficiency was continued in 1936 by a reduction in consumption of coal and coal equivalent of other fuels per kilowatt-hour generated to 1.44 pounds. Comparable amounts were 1.46 pounds in 1935, 1.69 pounds in 1929, and 3.2 pounds in 1919.⁵ Recent development of a new type of high-pressure steam turbine that generates additional current while still delivering enough exhaust steam to existing generators to keep them in normal operation has permitted increased output with only modest capital expenditure.⁶ To what extent a new type of multiple cable⁷ may affect the demand for copper for telephone lines in the future is difficult to say. Competition by aluminum doubtless was a factor in the development of a new type of hollow copper cable to transmit current of record high voltage from Boulder Dam to Los Angeles.⁸

Although still far below normal in activity, the construction industry made important gains in 1936, which aided materially in the business revival. The Federal Reserve index for value of total construction contracts awarded (based on data from F. W. Dodge Corporation) rose to 55 in 1936 compared with 37 in 1935 (1923-25 average=100), an increase of about 49 percent. Though achieving substantial gains in 1936, residential building lagged far behind all other types of construction activity combined. As a result of the comparatively low volume of construction, mineral industries supplying materials primarily used in building, such as brick, cement, lime, sand and gravel, gypsum, and building stone, were still considerably depressed. The possibility that construction costs would advance at a more rapid rate than income of potential builders threatened to curb effectively the upward trend now under way.

The farmers' situation continued to improve, in spite of another drought year, with a cash income estimated by the Bureau of Agricultural Economics at \$8,100,000,000 in 1936, compared with \$7,201,000,000 in 1935 and \$10,417,000,000 in 1929. This gain in his income was much greater than the rise in cost of manufactured goods he consumes, judging from available indexes, thus raising his net income and purchasing power. Mineral industries benefiting directly from increased farm income are those engaged in producing phosphate and potash (for fertilizers) and arsenic (for insecticides). Indirectly, the great majority of mineral industries gain through the farmers' larger purchases of automobiles, trucks, tractors, farm implements, gasoline, radios, electrical machinery, fencing, and the many other manufactured articles needed to improve his living and working conditions.

Improvement of conditions in these several domestic industries has been cited to show the basic reason for improvement in the mineral industries with which this volume is directly concerned.

The story is not complete, however, without a reference to increased foreign trade as an additional factor in recovery of the mineral extraction and processing enterprises. Exports of minerals, metals, and products (except gold, silver, and some minerals classed as chemicals,

together with machinery and motor vehicles) increased to \$597,000,000 in 1936, compared with \$536,000,000 in 1935 and \$1,276,000,000 in 1929. Imports increased at a more rapid rate to \$332,000,000 compared with \$281,000,000 in 1935 and \$702,000,000 in 1929. These totals for imports include the value of materials imported in bond for refining and export (important in the case of copper and less so in oil and other commodities), since these values automatically are listed by the Bureau of Foreign and Domestic Commerce as a domestic export, inasmuch as their form has been changed. Improvement in foreign trade in minerals is attributed to various factors, chiefly improved industrial conditions throughout the world, rearmament, and the effect of reciprocal trade agreements already negotiated by the United States acting as a wedge, at least, in the huge task of breaking down artificial and costly trade barriers.

Industrial employment and pay rolls in 1936 increased steadily and at a more rapid rate than the cost of living, resulting in a considerable increase in real wages to the average worker. Judging from Department of Labor indexes, the greatest increase in employment in important mineral-extraction industries was made in metalliferous mining, but substantial pay-roll gains were registered both in metalliferous and bituminous-coal mining. Unemployment, although considerably reduced, was still an important unsolved problem.

A continued moderate rise in annual average commodity prices in 1936 was led by raw materials and semimanufactured goods, both of which rose in price more rapidly than did finished products. Starting late in 1936, both ferrous and the common nonferrous metals began a spectacular price rise, which continued unabated into the first quarter of 1937. These advances represented in part the results of increasing costs of labor and materials used in their production, but for nonferrous metals the control was completely in the hands of the London Metal Exchange. War fears, with concomitant record peacetime rearmament programs, together with considerable speculative dealing, provided the impetus for the runaway market that developed in London for copper and lead and later for zinc and tin. Heavy forward buying, precipitated by the conviction that the upward trend would continue, accompanied the movement.

In general, stocks of important minerals and metals, particularly copper, lead, and zinc, in the United States were reduced materially in 1936. Bituminous-coal stocks in the hands of consumers and visible tin stocks were important exceptions; both rose substantially.

PRODUCTION

Trends in the production of important minerals and metals, plotted on ratio paper for convenient comparison of relative rate of change between different commodities, are shown for 1927-36 in figure 2. For the common metals, the figures represent primary production from domestic ores, with no secondary metal included. Aluminum gained most rapidly, with an increase of 88 percent, over 1935 production, copper followed with a 61-percent increase, and iron ore was a close third with a rise of 59 percent. Anthracite, with a gain of only 5 percent over 1935, made the poorest showing. New all-time records were made in production of crude petroleum and natural gas, whereas aluminum remained practically at the 1929 level and just below the 1930 record output. Silver output was back to the levels of the late

twenties, though still 20 percent below the record 1915 production; and gold output (including the Philippine Islands) was the best since 1916 and only 12 percent below the 1915 peak production. Compared with 1929 levels of output lead in 1936 still showed the poorest net recovery. The marked rise in output of bituminous coal reflected the spurt in iron and steel activity, increased power consumption, and the rise in commercial stocks.

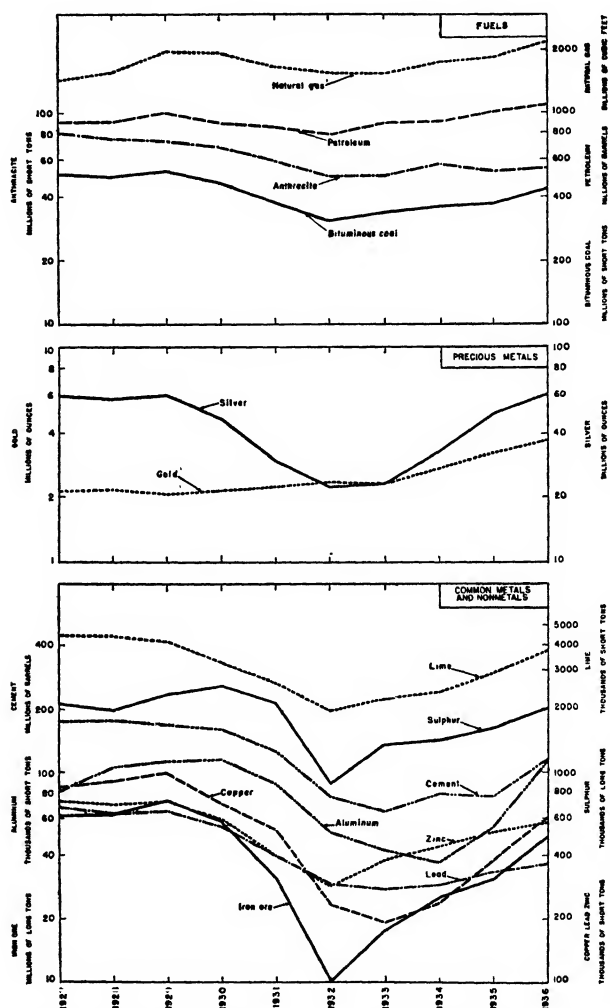

FIGURE 2.—Trends in production of important minerals and metals in the United States, 1927-36.

Trends in the production of minerals compared with the output of automobiles, iron and steel, and all manufactures, as indicated by index numbers compiled by the Federal Reserve Board, are shown in figure 3. The relative rise in 1936, compared with 1935, was virtually the same for minerals, automobiles, and all manufactures; the increase in iron and steel production far surpassed gains in the other fields shown. The monthly production record in 1936 of all minerals, total manu-

factures, iron and steel, automobiles, and cement, together with value of construction contracts awarded, as indicated by adjusted index numbers of the same agency, are shown in figure 4. Except for cement and construction contracts, most of the production levels lie slightly or well above the 1923-25 monthly average; the spectacular record of iron and steel is again evident.

FIGURE 3.—Comparison of trends of physical volume of production for minerals, iron and steel, automobiles, and all manufactures in the United States, 1928-36. All indexes from Federal Reserve Board data.

FIGURE 4.—Comparison of trends of physical volume of production for minerals, total manufactures, iron and steel, automobiles, and cement, and the value of construction contracts awarded in the United States in 1936, by months. All data from Federal Reserve Board; indexes adjusted for seasonal variation.

PRICES

Price trends of important minerals for 1927-36, on ratio paper for convenient comparison, appear in figure 5. The figures used in most instances represent average unit value received by the producers rather than average market quotations. The most marked increases for 1936 over 1935 are accredited to copper and zinc, with silver and lead only slightly behind. Probably the most striking feature of prices in the entire mineral field during 1936 was the control exercised over the copper and lead markets by the London Metal Exchange

during the latter part of the year and extending into 1937. General business revival, effected in part by record rearmament activities, coupled with recurring crises threatening world peace, made a perfect background for speculators, and prices for copper and lead started a pronounced upward climb during the latter part of 1936, culminating in an even more spectacular rise early in 1937, when zinc and tin followed suit. The average monthly price for electrolytic copper c. i. f. European ports rose from 9.10 cents per pound in June to 11.13

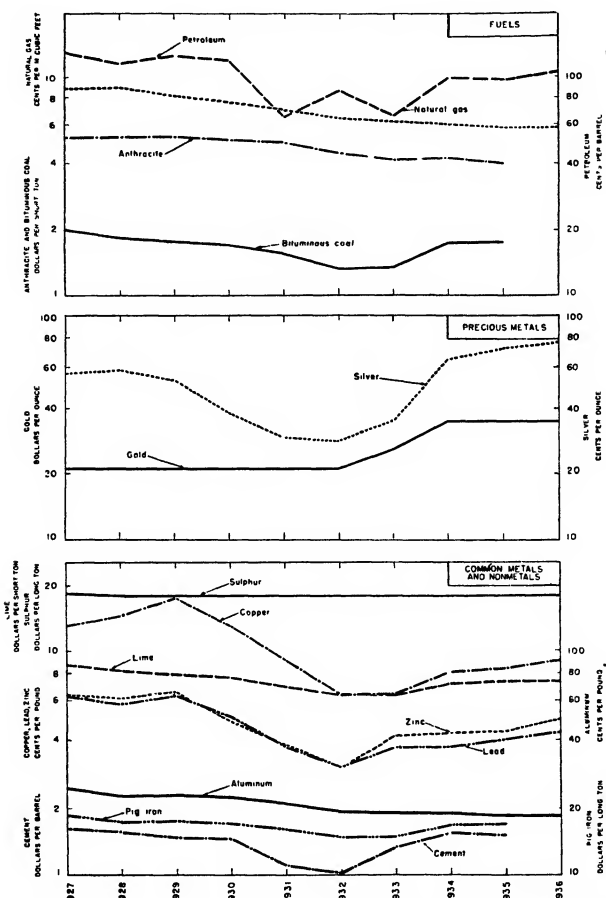

FIGURE 5.—Price trends of important minerals in the United States, 1927-36.

cents in December; pig lead for New York delivery rose from an average of 4.60 cents per pound in October to 5.55 cents in December. Zinc prices were sluggish in comparison, having risen only from an average of 5.16 cents per pound, New York, for prime western, in July to 5.65 cents in December. Much of the tonnage of copper produced during the latter part of the year doubtless was sold at prices substantially below those prevailing in the open market at the time of delivery, since heavy forward buying was made below the 10-cent level in midyear. Each advance in the London price was followed by a boost in the New York price, presumably to insure domestic con-

sumption of domestic copper supplies. This resulted in what was referred to by The London Mining Journal as a "vicious circle * * * of competitive advances between New York and London * * *."

Trends in the prices of fuels, metals, and cement compared with prices of all commodities, 1928-36, as measured by index numbers compiled by the Bureau of Labor Statistics, are shown in figures 6

FIGURE 6.—Comparison of trends of prices of mineral fuels and of all commodities in the United States, 1928-36. All data from Bureau of Labor Statistics.

and 7. The index for prices of petroleum products appears relatively low, because 1926, used as a base, witnessed the highest levels of petroleum prices since 1920.

The effect of the price rises of late 1936 in reopening dormant, relatively high-cost operations was not evident immediately, although announcements made at the year's end by several companies forecast

FIGURE 7.—Comparison of trends of prices of metals and cement and of all commodities in the United States, 1928-36. All data from Bureau of Labor Statistics.

a pronounced movement in this direction in 1937. Production at mines already in operation was increased gradually to practical capacity near the close of the year. It is almost axiomatic that greatest production occurs under high prices, and the smallest production under low prices. How well this statement is borne out for six important mineral commodities is shown in figure 8, in which production is plotted as ordinates and price as abscissas on separate charts for

copper, lead, zinc, portland cement, bituminous coal, and petroleum for 1922-36. Reasonably good straight-line trends from large production at high prices to small production at low prices are shown for copper, lead, zinc, and bituminous coal. Portland cement described a rather wide orbit, counterclockwise, as points were plotted from the early twenties to the middle thirties, the significant feature being the trend in the late twenties toward higher production at decreasing prices. The trend displayed by petroleum appears contrary to that shown by most of the other commodities, with a distinct tendency toward higher production at lower prices.

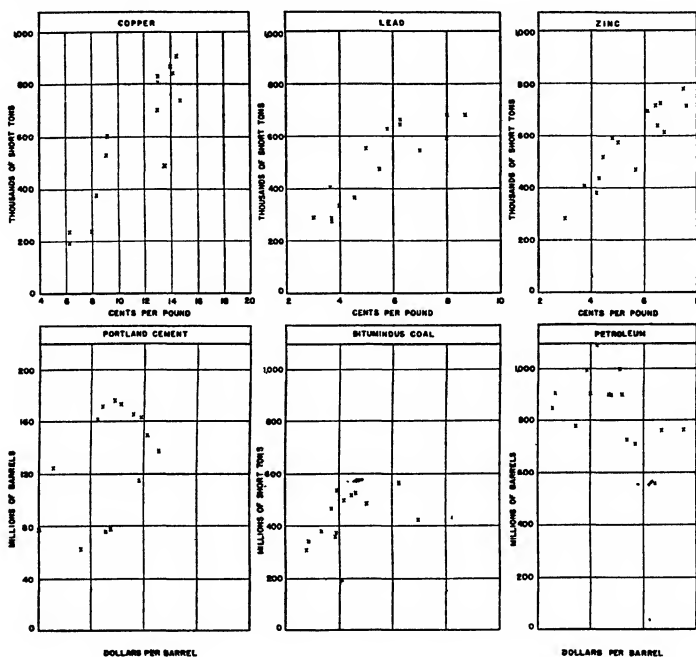

FIGURE 8.—Production at price, of important mineral commodities, 1923-36. Prices of portland cement and bituminous coal for 1936 not yet available and the 1936 point for each of these commodities is therefore omitted from the chart.

STOCKS

The tendency in 1936 toward reduction in stocks of important minerals was particularly marked for those held by producers of copper, lead, and zinc. (See fig. 9.) At the end of 1936 zinc stocks represented little better than a month's supply. The decrease in lead stocks was not quite as large, proportionately, as the depletion of copper and zinc stocks, but it was a healthy sign of improvement of the decidedly unhealthy stock situation as regards lead that still prevailed at the end of 1935. It should be clearly indicated that a considerable part of the reduction of producers' stocks of copper, lead, and zinc may have been and probably was accounted for by transfers to invisible stocks held in the hands of consumers. Unfortunately, no data are available to aid in exactly solving this problem, but reports from reliable sources indicate that for copper, such transfer of stocks was considerable. Visible supplies of tin in the United States, which had dropped to a very low level at the close of 1935, were at a much higher level at the end of 1936 but still represented

less than a month's supply. Bituminous coal held by consumers continued the increase evident since 1932. Uncertainty as to future supplies, due to the troubled labor situation at the close of the year, doubtless contributed to the increase of stocks. Stocks of iron ore at furnaces and lower lake ports, although slightly larger than at the close of 1935, were much lower than during the middle and late twenties. Stocks of iron ore at the mines, mainly in Michigan and Minnesota, were the smallest since 1907.

FIGURE 9.—Trends in mineral stocks in the United States, 1927-36.

EMPLOYMENT AND PAY ROLLS

Measured by the index numbers compiled by the Bureau of Labor Statistics, employment in mineral-extraction industries was still far below that in the entire manufacturing group in the upward move back to 1929 levels. Anthracite, metalliferous, and nonmetalliferous mining (including quarrying) still employed only 50 to 60 percent as many men as in 1929. Bituminous-coal mining and crude-petroleum-producing industries, while considerably better than the group cited, were still 20 to 25 percent below 1929 figures. Industries closely related to mining, including smelting and refining of metals and petroleum refining, showed in general a better record of employment than did all manufacturing. Employment in the cement industry was still about 36 percent less than in 1929.

FIGURE 10.—Trends in employment and pay rolls in mineral-extractive industries compared with all manufacturing industries, 1930-36. All data from Bureau of Labor Statistics; manufacturing indexes converted to 1929 as 100.

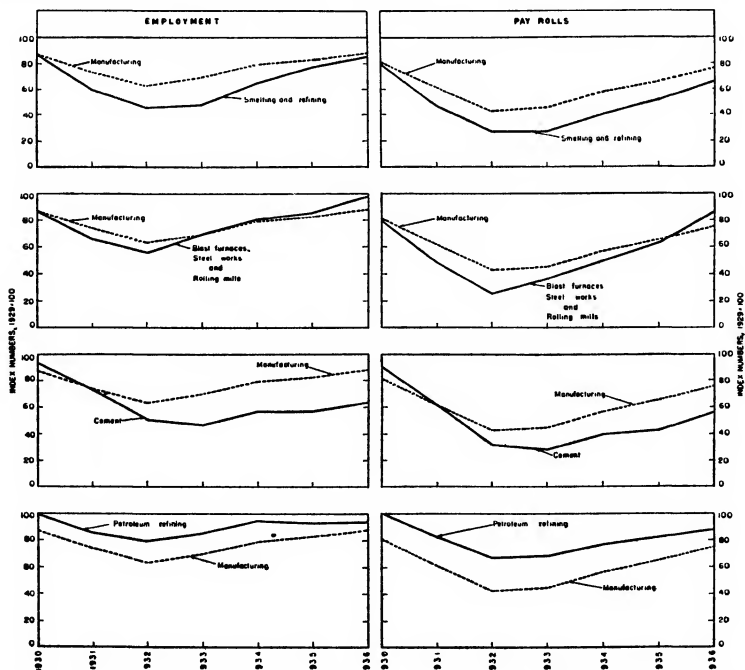

FIGURE 11.—Trends in employment and pay rolls in industries closely associated with mineral extraction compared with all manufacturing industries, 1930-36. Indexes converted to 1929 as 100.

The pay-roll trends follow fairly closely those for employment in the industries cited. Trends of employment and pay rolls in mineral-extractive industries compared with manufacturing for 1930-36, are shown in figure 10 and those for closely associated industries may be found in figure 11. The index numbers used in constructing the charts appear in the following table:

*Indexes of employment and pay rolls in mining and associated industries compared with indexes of employment in all manufacturing industries, 1930-36*¹

¹ All data from Bureau of Labor Statistics. Indexes for industries associated with mining and for manufacturing converted to 1929 as 100.

² Copper, lead, and zinc smelting and refining.

During 1936 the Bureau of Mines cooperated with the Census of Business in a canvass of mines and quarries for 1935 data on the most important items usually obtained in the decennial census of mines and quarries, including employment. Preliminary reports for various mineral industries have already been released, but summarized data for the entire mining and quarrying industry are still unavailable.

In October 1935 a National Research Program was established under the Works Progress Administration to collect and analyze information bearing on problems of employment, unemployment, and relief; and in December 1935 the individual project on Reemployment Opportunities and Recent Changes in Industrial Techniques was organized to inquire into the extent of recent changes in industrial techniques and to evaluate the effect of these changes on the volume of employment and unemployment. Aid of industry, labor, and Government and private agencies was enlisted; and since early in 1936 the Bureau of Mines has cooperated in the study of these problems as related to the mineral extractive industries.

Detailed study has been made of a considerable number of mineral industries wherein employment is a significant factor in the national picture, including coal, oil, iron, copper, lead, zinc, and silver, gold, cement, phosphate rock, gypsum, and stone. The general procedure

followed was to correlate employment and production data over a period of years to determine the trend of labor productivity in terms of units of material produced per man-hour or man-shift, followed by a study of the numerous variable factors important in determining the productivity trends. These studies are nearly completed, and some of the salient facts available are described in the chapter on Progress in Mine Mechanization.

A report⁹ issued early in 1937 summarized the problems in the study and presented preliminary findings for inclusion in the recent report of The National Resources Committee on Technological Trends and Their Social Implications. Exploratory trends presented on page 36 of the Weintraub report indicate that in mining, about 20 percent less labor would have been required for the same output in 1934 as was needed in 1920; and in manufacturing, about 44 percent less labor would have been needed in 1934 as was required in 1920 for the same output. Detailed results of these various productivity and employment studies will probably be available late in 1937.

An important phase of the study relating to the mineral extractive industries consisted of a resurvey of mechanical loading in underground and surface mines and quarries. Preliminary facts obtained on underground mechanical loading were presented in a recent paper.¹⁰

The first of the reports on the mineral industries released by this cooperative project appeared late in April 1937¹¹ and served as an introductory bird's-eye view to the problems to be discussed in greater detail for separate mineral industries in later reports. Tryon sums up the outlook for the next 10 years as follows:

In coal mining the forces making for labor displacement are strong enough to be a cause of some concern. In metal mining, also, the chances of expansion (in employment) beyond the level of the 1920's seem unfavorable. In oil and gas, on the other hand, the trends point to an increase in (total) labor requirements.

* * * Taking the mineral industries as a group, there seems little chance that the total demand for labor will rise greatly above the levels of the 1920's.

INCOME

Price increases for minerals and products, together with almost full capacity operations during the latter part of the year, caused a marked rise in the earnings of industries engaged in mineral extraction in 1936. The influence of the amount of output in controlling net income is a very important factor in mining, where overhead commonly is large on operations, whether they produce at high or low rates.

Preliminary figures compiled by the Bureau of Mines from data for individual companies published by Standard Statistics Co. reveal that 78 large companies engaged in mineral extraction and processing had a total net income of \$646,511,000 in 1936 compared with \$349,586,000 in 1935, an increase of about 85 percent. The total invested capital in 1935 was \$11,319,830,000, so that the proportion of net income to invested capital was about 5.7 percent in 1936, compared with 3.1 percent in 1935. These figures compare with an estimated proportion

⁹ Weintraub, David, and Posner, Harold L., *Unemployment and Increasing Productivity: National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques*, Philadelphia, Pa., March 1937, 76 pp.

¹¹ Tryon, F. G., Read, T. T., Heald, K. C., Rice, G. S., and Bowles, Oliver, *Technology and the Mineral Industries: Rept. E-1, Mineral Technology and Output-per-Man Studies, National Research Project, WPA, in cooperation with the U. S. Bureau of Mines, Philadelphia, Pa., April 1937.*

of earnings to invested capital of 9.2 percent for 403 industrial companies in 1936 compared with 5.9 percent in 1935. The 1929 figures were 8.8 percent for the same companies engaged in mineral extraction and processing and 10.6 percent for the same 403 industrial companies; the 1932 lows were -0.9 and 0.3 percent, respectively. Although earnings fell at a more rapid rate for mineral industries than for all industries during the depression, recovery has taken place at a faster pace also. The relative position of different branches of the mineral industry with regard to the relationship between net income and invested capital during the past 10 years is shown in the following table:

Percentage of net income or loss on invested capital of companies operating in various branches of the mining industry and in all industry, 1927-36¹

¹ Compiled from data published by Standard Statistics Co. Net income represents amount available after depreciation and fixed charges. Total invested capital includes funded debt, common and preferred stock, capital reserves, and surplus.

² Estimated by the Bureau of Mines on the basis of data for individual companies published by Standard Statistics Co.

³ Estimate based on the percent increase in profits of 933 corporations from 1935 to 1936, as shown by the Federal Reserve Bank of New York.

Coal companies in 1936 were still unable to show a consolidated net operating income; iron and steel and asphalt and cement companies exhibited modest returns of about 3.5 percent; oil producing and refining and common nonferrous metals (copper, lead, and zinc) producing companies earned returns of about 7 percent; and the highest returns, 9.4 percent, were made by a group of companies producing miscellaneous nonferrous metals. The greatest improvement in 1936 compared with 1935, was achieved by the iron and steel group, which attained better than a 400-percent increase.

It should be borne in mind that these figures represent only a sample of the entire mineral industry, and, furthermore, that a significant proportion of the companies included in the sample represents completely integrated units, from the mining of raw materials to the marketing of finished manufactured products. As an example, the 26 oil-producing companies, most of which are important refiners and marketers of products, earned about 67 percent of the net income in 1936 of the 78 mineral companies included in the sample.

Quite a different picture is revealed by the records of the Bureau of Internal Revenue, United States Treasury Department. Salient features of income, assets, and dividend payments of companies engaged in mining and quarrying, in manufacturing, and in construction are shown in the following table and in figures 12, 13, and 14.

Net income or deficit of corporations engaged in mining and quarrying, total manufacturing, and construction, 1924-34, in millions of dollars¹

Industry	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933	1934
Mining and quarrying.....	-66.9	243.6	272.3	29.4	125.3	232.1	-44.3	-254.8	-224.4	-176.4	-8.6

¹ All data from Statistics of Income (annual volumes), Bureau of Internal Revenue.

FIGURE 12.—Financial status of mining corporations in the United States, 1924-34. Data from Bureau of Internal Revenue.

It should be stated and emphasized at the outset that these statistics are not comparable with those included in the sample previously cited. The main feature in which they differ is that the sample includes large integrated steel and oil-refining industries under mining, whereas the Bureau of Internal Revenue includes these as subgroups under manufacturing. Although information on the net income of these subgroups is available in published form data on the total assets or liabilities and total cash and stock dividends declared by companies classified as subgroups under manufacturing are not available from published sources. Because of this, it was impossible to add these to the mineral extractive group to obtain better comparability.

Another feature in which the two sets of figures may differ materially is in the methods of determining what constitutes "net income." The figures taken from reports of the Bureau of Internal Revenue represent "statutory net income less statutory deficit" and do not include tax-exempt income under receipts or Federal income tax under deductions. Net income as generally computed by corporations in their operations reports includes the tax-exempt income under receipts and also the Federal income tax under deductions. Also, a few companies included in the sample report net income before depletion and other miscellaneous charges.

FIGURE 13.—Assets or liabilities, net income or deficit as percentage of assets or liabilities, dividend payments and cash dividend payments as percentage of assets or liabilities of mining corporations in the United States, 1924–33. Data from Bureau of Internal Revenue

FIGURE 14.—Net income or deficit, and cash dividend payments expressed as percentage of total assets or liabilities for mining, all manufacturing, and construction industries in the United States, 1924–33. Data from Bureau of Internal Revenue.

Despite limitations in comparing the two sets of figures and lack of details in Internal Revenue figures later than 1933, the data are presented to indicate general trends in important financial items for mining, manufacturing, and construction corporations for the 10 most recent years for which details are available.

The assets or liabilities shown include only those corporations that submit balance sheets. The percentages of net income or cash dividend payments to total assets for the different industrial groups shown are therefore a bit too high, since net income or cash dividend payments are totals for all corporations reporting, whether or not they submitted balance sheets. The difference is small, however, inasmuch as net income or deficit of corporations submitting balance sheets generally amounts to well over 90 percent of the total net income or deficit of all corporations reporting in the various groups covered.

The low level of the proportion of net income to total assets in mining and quarrying compared with total manufacturing and construction during the latter half of the twenties is a striking feature of figure 14. When industries engaged in manufacturing were enjoying average returns on income to total assets of from 5 to 7 percent, and those in construction were getting 3.5 to 6.5 percent, concerns engaged in mining and quarrying were averaging from -0.6 to only a little better than 2 percent.

In the matter of cash-dividend payments to total assets, mining and quarrying concerns have a somewhat better record when compared with those engaged in manufacturing and construction; but even here the showing is none too favorable.

NEW SECURITIES REGISTERED

Considerable information concerning new securities offered for sale by mineral extractive and related industries is now available from reports of the Securities and Exchange Commission. Details of new security offerings registered with the Commission by these industries and by all manufacturing industries (for purposes of comparison) from October 1, 1934, to June 30, 1935, and from July 1, 1935, to June 30, 1936, are given in the accompanying table:

Statistics of new securities fully effective under the Securities Act of 1933 registered by the Securities and Exchange Commission for mineral extractive industries, associated industries, and all manufacturing industries, Oct. 1, 1934, to June 30, 1935, and July 1, 1935, to June 30, 1936 ¹

[All figures in thousands, except first column, which shows the actual number of issues]

¹ First and second Annual Reports of the Securities and Exchange Commission.

² Included under manufacturing industries in S. E. C. tabulation and therefore in the total manufacturing listed herewith.

Perhaps the most striking feature shown by the figures is the huge increase in securities registered in the fiscal year 1936 compared with the last 9 months of the previous fiscal year. Of the mineral extractive industries, those engaged in metal mining have been by far the most active in offering new securities for sale. The principal intended use of the proceeds for the period October 1, 1934, to June 30, 1935, was for the purchase of plant and equipment, while in the fiscal year 1936 the principal intended use of the greatly enlarged proceeds was for repayment of indebtedness, although a considerable portion was also to be used for organization and development, purchase of plant and equipment, and increase of working capital. Of the industries closely associated with mineral extraction (many of them doubtless engaged in this type of operation in addition to manufacturing products therefrom), those engaged in iron and steel manufacturing offered the largest amount of new securities for registration, closely followed by petroleum refining companies. The principal intended use of the net proceeds by both these industrial groups was for repayment of indebtedness, although sizable amounts were intended for purchase of plant and equipment by the iron and steel industry in the fiscal year 1936.

Another point worthy of note is the dominant position of manufacturing industries associated with mineral extraction in the entire field of manufacturing, in regard to total securities registered. In the 9 months ended June 30, 1935, associated industries engaged in manufacturing registered 57 percent of the securities registered by all manufacturing concerns, and in the fiscal year 1936 the proportion increased to 60 percent.

From the time the Commission was created up to December 1936, mineral extractive industries were required to use the one general registration form applicable to all industries. Inadequacies in the form for handling special problems of mine financing were soon apparent; recognizing that better work could be done for both the mining industry and the investor, a new registration form was developed (form A-O-1), which was designed particularly for the problems inherent in financing gold and silver mines in the promotional stage, since the great preponderance of mine financing dealt with by the Commission concerned this type of enterprise. The new form became effective December 23, 1936. An explanation of the problems of the Commission in dealing with mine securities was presented by its then chairman, James M. Landis, at the Metal Mining Convention of the Western Division, American Mining Congress, Denver, Colo., October 1, 1936.¹²

GOVERNMENT MINING LOANS

Information received through the courtesy of the Reconstruction Finance Corporation indicates that from February 2, 1932, to May 21, 1937, inclusive, \$10,657,500 in loans has been authorized for use in mining, milling, and smelting enterprises. Of this amount, \$5,812,000 has been canceled or withdrawn, \$2,543,000 has not yet been disbursed, \$2,302,500 has been disbursed, and \$657,694 has been repaid. Details on amounts loaned for development and other purposes are shown in the following table:

¹² Landis, James M., *Mine Financing as Viewed by Securities and Exchange Commission*: Min. Cong. Jour., December 1936, pp. 11-13.

Loans made by the Reconstruction Finance Corporation to mining, milling, and smelting industries during the period Feb. 2, 1932, to May 21, 1937, inclusive

	Number	Institutions	Amount authorized	Withdrawals and cancellations	Proceeds not yet disbursed	Proceeds disbursed	Repayments	Proceeds disbursed less repayments
Development....	76	73	\$1, 272, 500	\$261, 000	\$558, 000	\$453, 500	\$22, 694	\$430, 806
Other.....	42	37	9, 385, 000	5, 551, 000	1, 985, 000	1, 849, 000	635, 000	1, 214, 000
	118	110	10, 657, 500	5, 812, 000	2, 543, 000	2, 302, 500	657, 694	1, 644, 806

From February 2, 1932, through May 22, 1937, the Corporation has also authorized loans to 28 coal companies amounting to \$6,250,976, of which \$2,504,992 has been withdrawn or canceled, \$2,484,515 disbursed, and \$141,655 repaid.

No loans have been authorized to firms or individuals engaged in petroleum production.

Further details concerning mining and other loans made by the Corporation may be found in its monthly and quarterly reports sent to Congress and available in printed form.

RESERVES

Early in 1936 a report ¹³ was released by the National Resources Committee, which summarized available information on reserves of 31 important minerals in the United States. The following excerpt from the foreword, pages 1 and 2, is a concise statement of the situation for important minerals as viewed by the authors:

Coal is perhaps our most abundant mineral resource. Beds now known, which can be mined under present conditions, have reserves sufficient to last 4,000 years. Iron ore, limestone, gypsum, aluminum, and molybdenum are also materials which will last far beyond any period for which we should feel concern. On the other hand, there are several minerals whose reserve life can only be measured by the decades, and in the cases of these very few decades will elapse before their exhaustion. Oil will last, at its present rate of consumption, for some 40 years, but changing economic needs and processes will alter the rate of use and consequently change the period of its depletion.

The reserves of lead, gold, and silver may last for a few decades only; lead and silver could, conceivably, be depleted in only 20 years. Copper, zinc, and fluor spar will probably last longer than lead and silver, but the period before their exhaustion will also be comparatively short. Many of the nonmetallics, such as china clay, graphite, mica, asbestos, and magnesite, exist in very large tonnages but, because of economic reasons or trade preferences, fail to capture the entire domestic market. Some of the conditions that have so far limited the production from this group of deposits will undoubtedly change in the future, and present unused deposits will be exploited. For another group of minerals the supply is already deficient; for some, such as nickel and tin, virtually nonexistent. The deficient list includes manganese, supplies of which are very small; chromite, which is in about an equal position; vanadium, known domestic reserves of which would supply the demand of this country for less than five years; mercury, which is the most erratic of metals and whose reserves are known to be small; and tungsten. These minerals are all necessities and our dependence upon foreign supplies either now or in the very near future must be recognized.

Discussion in much greater detail of reserves of individual minerals is given in the separate chapters through the report. An important factor to bear in mind is the approximate price level, which was considered in making the estimates for each mineral, as variable prices may change the availability of reserves in very large amounts.

¹³ Leith, Kenneth, and Liddell, Donald M., The Mineral Reserves of the United States and Its Capacity for Production: National Resources Committee, Washington, D. C., March 1936.

Many students of problems of mineral reserves may not agree with some of the conclusions stated in the report; however, it must be borne in mind that such a broad study necessarily was based largely on facts available in technical and business literature, supplemented by personal experience, correspondence, and information supplied by technical bureaus of the Government. Undoubtedly much pertinent information concerning the problem is available only to private individuals or companies, and it would indeed be a national benefit if more such data were made available.

In recent years considerable discussion has arisen concerning the possibility of exploiting low-grade mineral deposits, particularly those of which the United States has insufficient supplies for normal requirements, by means of the cheap power now available at Boulder Dam. During 1936 a Government report¹⁴ presented details concerning mineral supplies in this area. Summarized findings of the investigators as given on pages 4 and 5 are as follows:

This inquiry indicates that the region under consideration contains an uncommonly wide range of commercially valuable minerals and that some are present in great quantity of good grades and in part readily accessible by truck or railroad transportation to the area near the dam.

An appraisal of the resources may be expressed as follows:

A. Minerals or ores that have been found to be present in large quantity, of good or excellent quality, and readily accessible to transportation:

1. Nonferrous-metal ores: Lead-zinc or lead and zinc, Pioche, Yellow Pine (Goodsprings), Comet, Nev., and Wallapai, Ariz.; copper, Jerome, Ariz.
2. Ferrous-metal ores: Iron, Iron Springs (Desert Mound), Utah, and Baxter (Cave Canyon), Calif.; tungsten, Atolia, Calif., and Borianna, Ariz.
3. Nonmetallic minerals: Limestone, dolomite, gypsum, borates, celestite, salines (sodium chloride, sodium sulphate, sodium carbonate, potassium bromide, potassium chloride, calcium chloride), bleaching clays, refractory silica, and alunite.

B. Minerals or metals which have been found to be present in large quantity near a railroad but of a grade below that commonly considered acceptable and which may require new or uncommon methods of treatment before they can be marketed.

1. Nonferrous-metal ores: None.
2. Ferrous-metal ores: Manganese, Las Vegas (Three Kids), Nev.
3. Nonmetallic minerals: Magnesite, Muddy Mountains, Nev.; coal, Colob-Kanab field, Utah.

C. Minerals or metals which have been found to be present in large quantity and of good or excellent quality but which are remote from railroads that would insure cheap transportation to the dam area:

1. Nonferrous-metal ores: Eureka district, Arizona.
2. Ferrous-metal ores: Iron, Eagle Mountains, Kingston Mountains, San Bernardino County, Calif.; manganese, Artillery Peak, Mohave County, Ariz.
3. Nonmetallic minerals: Magnesite and brucite, Paradise Range, Nye County, Nev.

There are many districts in this region that contain noteworthy deposits of metals and nonmetallic minerals, some of which have already yielded a large production but will probably not contribute raw materials to industries near the dam. Included in this group would be numerous mines and districts whose principal product is gold or silver. Some of these, or groups of them, may when operated become potential consumers of power transported by trunk lines from Boulder Dam, but on the whole it is believed that the number will be small. These districts or groups of districts will reveal themselves by careful study of all the factors that determine success in operating mines. It is believed that the chief hope for markets for Boulder Dam power arising out of mining activities will lie in manufacturing industries located near the dam and using nearby mineral raw materials.

¹⁴ Mineral Resources of the Region Around Boulder Dam: U. S. Geol. Surv. Bull. 871, 1936.

LEGISLATION, INVESTIGATIONS, AND COURT DECISIONS AFFECTING THE MINERAL INDUSTRY

Legislation directly concerned with the mineral industry in 1936 centered around the attempt to pass the Bituminous Coal Act of 1936 (the so-called Guffey Act) in the closing days of the second session of the seventy-fourth Congress, following the decision of the United States Supreme Court in the *Carter Coal case* on May 18, 1936, that the Bituminous Coal Conservation Act of 1935 was unconstitutional. The 1936 Act (S. 4668 and H. R. 12800) was substantially a redraft of the act of 1935, with the labor regulations deleted from the bill, according to the view of the majority of the Court. Four of the Justices, including the Chief Justice, had held that the provisions of the code could be, and were intended to be, regarded as separable from the labor-control provisions and that the price-fixing provisions were a valid exercise of the authority of Congress under its power over interstate commerce. The 1936 act (H. R. 12800) was passed by the House on June 16, 1936, and was debated in the Senate. A filibuster by Senator Holt of West Virginia on the final day of the session, June 20, prevented action on the bill in the Senate.

Essentially the same bill came up for consideration in the first session of the seventy-fifth Congress and in a slightly modified form was passed by both Houses of Congress, agreed to in conference on April 12, 1937, and signed by the President April 26, 1937. The act establishes in the Department of the Interior a National Bituminous Coal Commission composed of seven members and a consumers' counsel, imposes a tax of 1 cent per net ton on the sale or other disposal of all bituminous coal produced in the United States, sets up a bituminous-coal code prescribing minimum and maximum prices and unfair methods of competition, exempts members of the code from payment of an excise tax of 19½ percent of the sale price or fair market value of all bituminous coal sold or otherwise disposed of which was produced in the United States, and charges the Commission with other duties, including investigation of methods of increasing the uses of coal, economic operation of mines looking toward coal conservation, safe operation of mines to minimize working hazards, and problems of marketing in order to decrease distributing costs for consumers' benefits.

The Faddis-Barbour tin bill (Public Law, 448, 74th Cong.), passed by the Senate in 1935, was passed by the House February 3, 1936, and approved by the President February 15, 1936. To provide for the protection and preservation of domestic sources of tin, the law prohibits the exportation of tin-plate scrap from the United States except upon license issued by the President. On February 16, 1936, the President issued an Executive order that delegated his licensing authority under the act to the National Munitions Control Board; and on April 4, 1936, the Secretary of State issued regulations defining tin-plate scrap, prohibiting export licensing from April 16 to July 1, 1936, and presenting forms that must be filled out in applying for export licenses to be granted by the National Munitions Control Board after July 1, 1936, providing their issuance is consistent with the purposes of the act.

Other laws enacted in 1936, important to all business, including the mineral industry, included the Revenue Act of 1936, the most controversial new feature of which consisted of a graduated surtax on

undistributed net income; the Government Contract Labor Standards Act of 1936 (the Walsh-Healy Act), which required that firms contracting for sale of materials, supplies, or equipment to the Federal Government or any agency thereof in amounts exceeding \$10,000 be required to comply with certain labor provisions, including minimum wages, the 40-hour week, and no child labor, the Secretary of Labor having been designated as supervising agent of the Government to administer the act; and the Anti-Price Discrimination Act of 1936 (the Robinson-Patman bill), which authorized the Federal Trade Commission to investigate and prohibit discriminations in price where they may substantially decrease competition or tend to create a monopoly in interstate commerce, and made the recipient of an illegal price discrimination equally guilty with the person who granted it.

Federal legislation under serious consideration in 1936 of vital interest to the mineral industry included two bills dealing with stream pollution; and a bill providing transfer to the States of public lands, contained therein, including minerals, subject to certain conditions.

Early in 1936 several resolutions were introduced in Congress calling for thorough investigations of health conditions in connection with mining or tunneling operations. In accordance with the one introduced by Representative Marcantonio (H. J. Res. 449), a general survey of silicosis problems was undertaken by the Secretary of Labor. Conferences were held in February and May 1936, and committees were appointed to study the medical and engineering methods of prevention and the economic, legal, and insurance aspects of silicosis. Officials of the United States Bureau of Mines and the Public Health Service presented much information in connection with these investigations.

Legislation of particular interest to the mineral industry under consideration during the first session of the Seventy-fifth Congress included, in addition to the bituminous-coal control bill already discussed, stream-pollution bills similar to those introduced in 1936, one of which (H. R. 2711) passed the House on April 21, 1937, and at the time of writing is now subject to Senate action; several bills prohibiting export of iron and steel scrap, except under license; an amendment to the Navy Department appropriation bill authorizing expenditure of \$3,500,000 for the purchase of strategic minerals; and the Connally bill, continuing indefinitely Federal control of "hot oil" shipments in interstate or foreign commerce, which passed the Senate early in 1937 and was referred to the House for consideration. A live subject, still unsettled June 1, 1937, is the fate of the excise taxes on imported copper, coal, and petroleum, which expire on June 30 according to provisions of the Revenue Act of 1934.

Decisions of vital importance to all industry in the United States were handed down by the United States Supreme Court when, in April 1937, the National Labor Relations Act (Wagner Act) was upheld, and in May 1937 the Social Security Act was also declared constitutional.

FOREIGN TRADE

Foreign trade in minerals in 1936 was featured by a continuation of the steady improvement of the 3 previous years, exports in 1936 amounting to \$596,619,000 compared with \$535,607,000 in 1935, a gain of about 11 percent. Imports increased more sharply, from \$280,992,000 in 1935 to \$332,217,000 in 1936, a gain of 18 percent. The gain in trade of minerals, as of all merchandise, over 1935 would have been much more marked had it not been for the shipping strike which completely paralyzed all foreign trade in merchandise on the Pacific coast from November 1, 1936, to February 3, 1937, and which interfered to a serious extent with shipping operations on the Atlantic and Gulf coasts over the same period.

FIGURE 15.—Trends in the value of imports and exports of minerals and their products compared with all merchandise, 1927-36. Data from Bureau of Foreign and Domestic Commerce.

These figures represent the totals of group 5 (nonmetallic minerals) and group 6 (metals and manufactures, except machinery and vehicles) as compiled by the Bureau of Foreign and Domestic Commerce. Included, therefore, are semimanufactures and even advanced manufactures of both nonmetallic minerals and metals, except machinery and vehicles, so that the data by no means show United States trade in crude or raw mineral materials alone. Furthermore, a number of raw and semimanufactured minerals classified by the Bureau of Foreign and Domestic Commerce as chemicals, such as coal tar and products, borax, soda ash, carbon black, nitrate, phosphate, potash, and others, are not included. A complete retabulation of the entire import-export schedule relating to minerals and chemicals, excluding advanced manufactures and including various minerals classed as chemicals, would be necessary to depict the exact situation. The total value figures presented should be understood, therefore, as merely indicating broad trends.

The following principal commodities comprised about 83 percent of the value of our exports of minerals and products in 1936:

	<i>Value</i>	<i>Percent of total value</i>
Petroleum and products.....	\$260,800,000	43.7
Anthracite and bituminous coal.....	52,400,000	8.8
Refined copper (mainly of foreign origin).....	40,700,000	6.8
Iron and steel advanced manufactures.....	37,900,000	6.3
Steel mill manufactures.....	32,000,000	5.4
Tin plate.....	23,500,000	3.9
Iron and steel scrap.....	21,800,000	3.7
Steel sheets.....	14,500,000	2.4
Crude sulphur.....	10,100,000	1.7
Undistributed.....	102,900,000	17.3
Total minerals.....	596,600,000	100.0

In the petroleum and products group, refined oils constituted the principal value at \$176,700,000, with crude oil at \$66,100,000; and of the refined oils, lubricating oil was the largest item, ahead of gasoline. Exports of bituminous coal (\$38,600,000) were considerably more important than those of anthracite (\$13,800,000). Exports of refined copper consist very largely of blister imported in bond for refining and export; since its form is changed in the United States, it is classed as a domestic export even though it is dominantly of foreign origin. The important position of iron and steel, including semimanufactures, steel-mill manufactures, and advanced manufactures, in our mineral export trade is shown by the table.

Increases in exports were well distributed, although outstanding examples of larger-than-average gains comprised tin plate, with an increase of 80 percent in value and 75 percent in quantity, and sulphur, with value and quantity increases of about 34 percent. Exports of refined copper (mainly of foreign origin) fell off 15 percent in quantity, with the value remaining about the same, due to higher prices.

The following principal commodities comprised 75 percent of the value of our imports of minerals and products in 1936:

	<i>Value</i>	<i>Percent of total value</i>
Tin.....	\$75,500,000	23.0
Petroleum and products.....	40,200,000	12.0
Diamonds.....	33,300,000	10.0
Copper (mainly in bond for refining and export).....	29,900,000	9.0
Nickel.....	23,800,000	7.0
Ferro-alloys.....	20,600,000	6.0
Steel-mill manufactures.....	13,100,000	4.0
Iron and steel semimanufactures.....	8,400,000	2.5
Iron ore.....	5,300,000	1.5
Undistributed.....	82,100,000	25.0
Total minerals.....	332,200,000	100.0

Of the total copper shown under imports in 1936, 88.5 percent of the value and 87 percent of the quantity consisted of copper in the form of ore, matte, or blister (mainly blister), which was imported in bond for refining and export. Only minor amounts actually enter the United States for consumption over the 4-cent-per-pound excise tax on imports. Of petroleum and products imported in 1936, about 54 percent of the value consisted of crude oil and about 41 percent of advanced and refined oils. Cut but unset diamonds comprised 68 percent of the value of all diamonds imported in 1936. Of the ferro-

alloys, manganese ore and ferromanganese constituted more than half and chrome about 21 percent of the total value.

Import gains likewise were well distributed, although better than average increases were shown by the following commodities: Abrasives increased 28 percent in value; asbestos and manufactures, 47 percent; cut but unset diamonds, 46 percent; ferro-alloys, 63 percent; and nickel, 39 percent. Imports of copper in bond for refining and export decreased 14 percent in value and 28 percent in quantity in 1936 compared with 1935.

For the first time since 1893 the value of all merchandise imported into the United States was greater than that exported. This doubtless indicates greatly improved industrial conditions in the United States, coupled with the drought, tending to increase imports more rapidly than exports, which are still hampered by nationalistic policies, exchange control barriers, and other discriminatory trade measures in many world markets of great importance in our earlier foreign trade.

Another factor of great importance in improving United States foreign trade has been the reciprocal trade agreements program. Fifteen agreements had been concluded up to December 31, 1936, all of which were in effect at that time. Ten of the agreements became effective during 1936.

IMPORTANT FOREIGN DEVELOPMENTS AFFECTING MINERALS

The outstanding foreign development of 1936 affecting minerals was the competition in world rearmament prompted by increasing fears of a general outbreak of hostilities between important world powers. Incidents arising from the application and attempted enforcement of sanctions against Italy at times increased this tension. This source of friction was removed by withdrawal of sanctions in July 1936, following Italian victories in Ethiopia; but other serious troubles soon arose in the form of the Spanish rebellion and the demands of Germany and Italy for a more equitable share of world raw materials to ease the serious condition of their domestic economy. The swift rearmament race of the past year or two was culminated early in 1937 by the announcement by Great Britain of a vast rearmament program involving the expenditure of approximately £1,500,000,000 in the next 5 years. The effect on industrial recovery of these huge armament expenditures, which, according to a German estimate dispatched to the *New York Times*,¹⁵ accounted for 11 percent of the world's industrial production in 1936 compared with only 4 percent during the war and during the 1920's, has been most profound. Great advances in mechanization of military and naval operations during the past two decades have increased the importance of minerals in such operations and hence in a preparedness program. The use of metals for these purposes was just making itself felt in 1936 in world-consumption statistics, and 1937 should certainly offer additional evidence of the influence this factor exerts in any present-day analysis of the consumption of mineral commodities.

During 1936 the position of the gold-bloc countries became steadily worse, until, on September 25, an announcement was made by the

¹⁵ Case, Winthrop W., *World Recovery Goes Forward Despite Trend Toward Economic Nationalism: Annalist*, Jan. 22, 1937, p. 131.

United States Treasury that an agreement had been reached between the Governments of Great Britain, France, and the United States as to a policy for maintaining the greatest possible equilibrium in the system of international exchange and by relaxing progressively the present system of quotas and exchange controls with a view to their ultimate abandonment. Shortly after this, and as a result thereof, action by France, Switzerland, the Netherlands, and Italy in devaluing their currencies brought back their exchange rates roughly to the levels in relation to the dollar and sterling that prevailed before the abandonment of the gold standard by Great Britain in 1931. This was an important step toward a much more general revival of international trade.

Cartels.—International control agreements (cartels) of one kind or another continued to operate in production of tin, copper, aluminum, cobalt, magnesite, and potash.

The restriction agreement covering tin was due to expire at the end of 1936. Negotiations to renew the agreement were undertaken during the year, and finally, on January 5, 1937, official announcement was made that a new plan had been accepted by all countries signatory to the original agreement, to be effective for 5 years starting January 1, 1937.

The copper curtailment agreement, made in 1935, continued in effective operation in 1936, the parties thereto being the large producers in Chile, Belgian Congo, and Rhodesia. Up until August the rate of production continued at 70 percent of the original agreed capacity. Successive increases in production quotas were made until, at the close of 1936, the rate was 105 percent of "capacity" fixed by the original agreement. Early in 1937 all restrictions were removed when the copper market developed runaway tendencies, but reports in May indicate that attempts are being made to renew restriction.

Efforts were made during 1936 to renew the zinc cartel, which had terminated in 1934, but difficulties resulting from nationalistic programs aimed at self-sufficiency were too great and results were negative.

The quicksilver cartel was terminated in December 1936, presumably because of the tense feeling between Spanish loyalists, still in control of the Almaden mine, and the Italians.

PROGRESS IN MINE MECHANIZATION

MINERAL-TECHNOLOGY AND OUTPUT-PER-MAN STUDIES

By O. E. KIESSLING AND F. G. TRYON ¹

Among the complex factors that have contributed to the economic advance of the United States during the last half century, few have been more important than the ability of the mining industry to provide an increasing abundance of raw materials of the underearth at declining cost. More than 50 years have now elapsed since the creation of the United States Geological Survey in 1879 set in motion an inventory of the national resources of minerals and a systematic record of their utilization. The period since then has been marked by many changes, particularly by the discovery of new deposits. Although the golden age of surface prospecting for the metals has now drawn to a close and the day of the old-time prospector seems nearly over, new methods of applying geology and physics to the task of exploration continue to yield discoveries of minerals, particularly petroleum and natural gas, and may in time add greatly to the Nation's store of metal as well.

Evidence of increasing depletion.—The period since 1879 has also been marked by progressive depletion, which in some branches has

¹ This report by members of the Bureau of Mines staff was made possible by the cooperative arrangement between the Bureau of Mines and the Works Progress Administration's National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques. Results of this cooperative effort are reviewed both by Bureau officials and by David Weintraub and Irving Kaplan, respectively Director and Associate Director of the National Research Project, WPA.

largely offset the contributions of mineral discovery. Many once-famous metal camps have reached an old age that even \$35 gold cannot rejuvenate. Other districts that still rank as major producers show clearly the handicaps of depletion. Gold mines on the Mother Lode are down to 5,300 feet. Butte has touched a depth of 4,100 feet. Magma at 3,600 feet and the Morning mine at 5,400 feet are in districts where increasing depth is a factor to be reckoned with. Michigan, earliest among the great copper districts, has reached depths of 6,200 feet, quite the deepest levels at which men have tried to win the base metals anywhere in the world. Meantime the average grade of ore mined has declined. The average yield of mercury per ton of ore has dropped from 2.92 percent (New Almaden mine) in 1880 to 0.30 percent in 1929. The average yield of copper has fallen from about 60.2 pounds per ton of ore in 1880 (68.4 pounds in 1889, when Montana began to assume a more important place in production) to 28.2 pounds in 1929.² In oil and gas the brilliant discoveries of new fields in the Southwest and California mask the impending exhaustion of many hundred old ones, and even in the bituminous-coal fields there are districts in which the finest seams are nearing exhaustion. In anthracite mining, 29 percent of the reserves are exhausted; from 1872 to 1935 the average depth of workings has doubled, and the average thickness of the beds mined has been cut in half.³ In addition, the problem of mine drainage has so increased that today 33 tons of water must be pumped from the mines for every ton of anthracite raised from underground.⁴

Some day depletion is likely to force a general increase in mining costs and in the price of mineral products. But thus far, with some exceptions, mineral technology has succeeded in offsetting the pressure of depletion and, broadly, in reducing both costs and prices. Cost comparisons in dollars and cents are much affected by changes in the purchasing power of the dollar and in wage rates, but except for the munitions shortage that accompanied the World War, mineral prices have shown a long-time downward trend in relation to the all-commodity price index. In the years since 1879 the metals, especially, have dropped many points in comparison with the general level of prices.⁵

Large gains in efficiency.—This decline of mineral prices in the face of the growing handicaps of depletion has been made possible by great advances in efficiency. The changes are best measured in the output per man. In iron-ore mining, productivity per man increased from 234 tons in 1880 to 2,560 in 1929. In coal mining—anthracite and bituminous—the increase was from 422 to 930 tons; in copper mining, from 9,290 to 44,900 pounds of metal; and in the production of phosphate rock, from 90 to 1,206 tons.⁶ In several branches of mining, the increasing output per worker has been especially rapid in the period since the war. For the minerals as a group, however, the rate of increase has often fallen short of that in manufactured goods.

The advance of mineral technology is a subject of deepest interest to the Bureau of Mines and to practical mining men.⁷ Next to the primary records of production and demand, the most important barometers of change in the mining industry are the trends in the use of manpower and in underground methods and equipment. For this reason the Economics Branch of the Bureau is seeking to develop adequate records of the labor force required in mining, of the man-hours expended per ton of product, installed horsepower, power consumed, tonnages produced by various mining systems, and mechanical equipment.

Mechanization progress studied by WPA.—A beginning has been made in the analysis of these factors, particularly in coal mining. When, therefore, the Bureau was asked by David Weintraub, Director, National Research Project of the Works Progress Administration, to cooperate in a study of reemployment opportunities and recent changes in industrial techniques, the invitation could hardly be declined. The cooperation of the Works Progress Administration has enabled the Bureau to supplement its own resources of data and to recruit enough workers to review systematically the trends of output per man in the light of changing technology. Preliminary reports on certain phases of the inquiry have already been made.⁸ Detailed studies tracing the changes in output per worker, mechanical equipment, and mining methods are in process that will cover anthracite and bituminous coal, petroleum and natural gas, iron, copper, lead and zinc, phosphate rock, crushed stone, and certain other mineral industries.

In many branches of mining, it is found that progress in underground technology has centered largely in the art of handling ground, the peculiar province of the mining engineer. This is illustrated by the shrinkage or caving methods developed to work massive ore bodies, such as the low-grade porphyry coppers.

But along with these methods have come remarkable advances in the mechanization of tasks formerly done by hand. Improvements in mechanical equipment have characterized all departments of mining; but in the period since the war the outstanding development in mechanization below ground has been the replacement of hand shoveling by scrapers or power shovels. Any account of mining technology and its effects on requirements of manpower during the postwar years is therefore largely concerned with the application of mechanical loading.

Two ways of measuring advances in the use of machinery present themselves. The first is to ask mine operators to report the number and type of machines in use and the tonnage handled therewith. Operating records for certain kinds of machinery in the coal mines have been kept since 1891. Coal-cutting machines were introduced in the eighties. From 5 percent in 1891, the year of the first survey, the proportion of the national output of bituminous coal cut by machine has increased to 84 percent in 1935, a proportion now close to the saturation point, though improvements in the speed and efficiency of the machines are expected to continue. The improvement

⁷ The lively interest in this field is indicated by the expositions held periodically by the American Mining Congress, at which manufacturers of mining equipment display their newest wares to literally thousands of coal- and metal-mine operators.

⁸ Tryon, F. G., Read, T. T., Heald, K. C., Rice, G. S., and Bowles, Oliver, work cited (footnote 5); also, Merrill, C. W., Henderson, Chas. W., and Kiessling, O. E., *Small-Scale Placer Mines as a Source of Livelihood* in 1935, Rept. E-2, Mineral Technology and Output-Per-Man Study, National Research Project, WPA, in cooperation with the U. S. Bureau of Mines, Philadelphia, Pa., May 1937.

in performance attained meanwhile is indicated by the increase in daily tonnage per machine from 51 in 1891 to 136 in 1935.

Thirty years later mechanical loaders first entered the field. The initial systematic record of numbers of loading machines used was reported by the coal-mine operators to the Bureau of Mines in 1923. At that time the tonnage of bituminous coal loaded mechanically was found to be 1,879,000 tons, reported by 60 mines. From this level the tonnage mechanically loaded increased to 47,177,000 tons, produced by 317 mines in 1935.

Recording mechanical equipment as a feature of the annual statistics of mine operation has proved of wide interest to the coal industry, and the Bureau plans to extend it to metal mining and the production of the nonmetals as well. However building up complete records from the operating side requires many months of correspondence and field work because of the great number of mines to be covered and the necessity of accounting for all before the inventory of equipment can be deemed complete. With 6,300 producing units to be canvassed in the bituminous-coal industry alone, plus several thousand metal mines, large and small, and other thousands of nonmetallic operations, a direct census of mines and quarries necessarily consumes months or years.

Manufacturers' reports as index of trends.—Fortunately, there is an alternative way to ascertain quickly the outstanding changes in mechanization—to draw upon the experience of equipment manufacturers. Twenty-eight manufacturers produce 99 percent or more of the loading equipment supplied to coal mines in the United States, and even fewer fill the needs of the metal mines and quarries for such equipment. If manufacturers are disposed to cooperate and appreciate the importance of such records, a bird's-eye view of the change in mechanical equipment can be obtained easily and quickly. Where the census of mines themselves takes many months, a summary of manufacturers' shipments can be completed soon after the new year.

The two papers that follow illustrate the possibilities of such manufacturers' reports as an index of the advance in mining practice. The first, dealing with mechanical loading in coal mines down to the end of 1936, was completed and published on February 10, 1937. The second, which deals with metal mines, covered a wholly uncharted field; yet here a substantially complete count down to the end of 1936 was in print by May 15. The preliminary articles, made available to the mining industry by courtesy of *The Mining Congress Journal*⁹ and the *Engineering and Mining Journal*,¹⁰ are here given in more detail.

Records of manufacturers' shipments are not a substitute for operating records of machine performance, but the two supplement each other usefully. With the help of the mining companies that furnish information on production, the Bureau will spare no effort to develop for all branches of mining adequate records of machine equipment, man-hours and kilowatt power-hours per ton, as well as additional information on operating performance. Reports of manufacturers' shipments improve the accuracy of this work and permit early determination of trends. It is hoped that the following surveys can

⁹ Plein, L. N., and Tryon, F. G., sales of Mechanical Loading and Cleaning Equipment for Use in Coal Mines in 1936: *Min. Cong. Jour.*, February 1937, pp. 57-60.

be continued in the future, maintaining an up-to-date indicator of technical progress.

MECHANICAL LOADING IN COAL MINES

By L. N. PLEIN AND F. G. TRYON

Total units sold in 1936.—A substantial increase in the use of mechanical loading devices in both anthracite and bituminous-coal mines is indicated by manufacturers' shipments in 1936.

Reports courteously furnished by 28 manufacturers are summarized in the following table. Sales of mobile loaders reached a total of 344 units, nearly treble the figure for 1935 and larger than that reported in any previous year. Sales of conveyors were reported as 972 units, an increase of 47 percent over the year preceding. Sales of scrapers or scraper hoists increased 27.3 percent. Sales of pit-car loaders, on the other hand, were less than in the year before.

Units of mechanized loading equipment sold to anthracite and bituminous-coal mines, as reported by identical manufacturers, 1933 to 1936, inclusive

	1933	1934	1935	1936	Percent increase (+) or decrease (-), 1936 over 1935
Mobile loaders.....	41	55	115	344	+199.1
Scrapers.....	65	34	22	28	+27.3
Conveyors ¹	384	596	661	972	+47.0
Pit-car loaders.....	18	26	28	11	-60.7

¹ Includes hand-loaded conveyors and conveyors equipped with duckbills and other self-loading heads.

Total sales, by States.—Shipments of mechanized loading devices of one type or another were made to 19 States in 1936. Nearly every important producing State is represented in the list. In many of the smaller States it is impossible to show the number of machines of each type sold without disclosing the business of individual manufacturers. However, the total number of units shipped to each State or region during the year is listed below. The kinds of machines sold are indicated in a parallel column, the abbreviation L standing for mobile loaders, S for scrapers, P for pit-car loaders, and C for all types of conveyors, including those equipped with loading heads. The several types are arranged in the rough order of their capacity. Thus, for Ohio a total of 72 units is shown, followed by the letters L, C, and P, indicating that the highest capacity was in the form of mobile loaders, followed by conveyors and pit-car loaders.

Total number of units of mechanized loading equipment shipped for use in each State or region in 1936

¹ Includes a few units in western Kentucky.

Installations versus replacements.—A point of much interest is the extent to which sales of equipment represent replacement of old machines, as opposed to new installations. The information collected did not separate replacements accurately, but some light is thrown on the question by classifying the purchasing companies into those that had made use of equipment of the type sold during the preceding year and those that had not. This is done in the following tabulation. Thus, it was found that a total of 101 bituminous-coal-mining companies had received shipments of mobile loaders in 1936. Of these, 39 companies had made use of mobile loaders during 1935. There were, however, 62 other companies buying mobile loaders in 1936 that used none in 1935. The separation is not clear-cut, since numerous mining companies that used mobile loaders in 1935 bought more machines in 1936. On the other hand, there were doubtless mines that purchased machines in 1936 to replace loaders bought some years ago and not used in 1935. The table, however, is sufficient to indicate that the bulk of shipments in 1936 undoubtedly represented additions rather than replacements.

A similar conclusion is indicated by the record of shipments of conveyors.

¹ In addition, 8 companies bought scrapers, of whom 3 used scrapers in 1935 and 5 did not. Also, 5 companies bought pit-car loaders, of which 2 used pit-car loaders in 1935 and 3 did not.

² Includes conveyors equipped with duckbills and other self-loading heads, and hand-loaded conveyors other than pit-car loaders.

Units shipped compared with units in use.—The changing demand for the several major types of equipment is indicated by the following table comparing the number of units in use from 1928 to 1935, inclusive, with new shipments in 1936. The number of mobile loaders in active use, as reported by bituminous mine operators, increased from 397 in 1928 to 657 in 1935. The shipment of 344 mobile loaders during 1936 was thus equivalent to more than half the total number previously in use. The shipment of conveyors in 1936 likewise constituted a large fraction of the number previously installed, as reported by the operators, especially in the bituminous fields. Because of uncertainties in definition of what constitutes a conveyor, the record of sales is not wholly comparable with the record of the number previously in use, but the fact of a large increase is clear. The number of scrapers sold, despite the increase over 1935 sales, was comparatively small compared with the numbers previously used. In the bituminous fields, the number of scrapers in use reached a peak in 1930 and has since declined. In the anthracite fields, the number of scrapers continued to increase down to 1934, declining slightly in 1935. Installations of pit-car loaders reached a maximum in 1931 and have since declined in both the bituminous-coal and anthracite mines.

¹ Number of units not reported in these years.

² Reported as "conveyors (room, face, and entry)", "shaker drives", and "duckbills." The figures of number sold in 1936 are not exactly comparable with the number in use in 1935, because of uncertainties in defining what constitutes a conveyor.

³ Represents number of bituminous mining companies to whom conveyors were sold in 1936. Of these, 32 companies were mining with conveyors in 1935, and 84 were not.

Percent of deep-mined output mechanized.—In 1935, over the country as a whole, 13.5 percent of the underground production of bituminous coal and 21.2 of the anthracite was loaded with the aid of mechanical devices. The figures include coal handled on pit-car loaders and hand-loaded conveyors as well as with mobile loaders, scrapers, and duckbills. In the past, the geographical distribution of mechanical loading has been much affected by physical conditions and by differentials in wage rates. The areas where mechanization had advanced farthest down to the end of 1935 were the Northern Rocky Mountain States, Illinois, and Indiana, areas where seam conditions were favorable and where, during the period from 1923 to 1933, wage rates, by comparison with the southern and eastern fields, were relatively high. In 1935, 89.8 percent of the deep-mined output of Wyoming was mechanically loaded. In Montana, the proportion was 80.1 percent, in Indiana 62.5, and in Illinois 55.3. In the Appalachian States, on the other hand, the proportion mechanically loaded was much smaller, though a few companies had successfully applied mechanization there, also. In 1935, the proportion of the West Virginia output mechanically loaded was 2.1 percent and that of Kentucky 1.3 (table 25, chapter of Yearbook on Coal).

Regional distribution of mechanized capacity.—Recently, market conditions and the trend of wage rates have tended to stimulate mechanization in the Appalachian region, and a large part of the sales of equipment reported by manufacturers in 1936 went to the bituminous fields of the East and South. Figure 16 shows, in generalized form, the regional distribution of sales in relation to preexisting capacity. In this map the tonnage loaded mechanically by all devices

in 1935 is shown by the black columns. To these has been added in white a rough indication of the capacity of the equipment purchased in 1936.¹¹ Accurate figures of the increase in actual tonnage mechanically loaded must await the detailed reports of mine operations during the year, but meanwhile the map may suffice to indicate the areas where sales of equipment were most active.

The largest installations of mechanical loading equipment seem to have been made in West Virginia, where the monthly report of the State department of mines gives a current record of the increase in tonnage mechanically mined. During 1936, 2,353,729 tons of coal were loaded on conveyors in the State, and 6,348,920 tons were produced by mobile loaders, scrapers, and other devices eliminating hand shoveling. The total loaded with the aid of mechanical devices was thus 8,702,649 tons for the year. In 1935, the total for the State, as reported to the United States Bureau of Mines, was 2,059,322 tons.

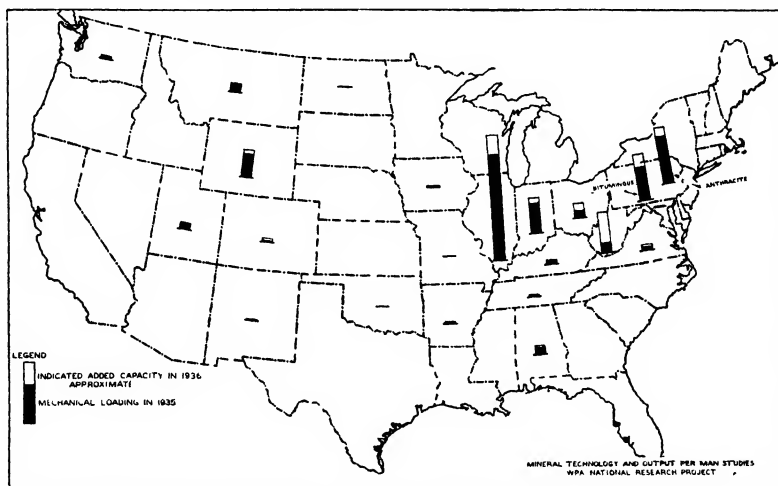

FIGURE 16.—Tonnage of coal mechanically loaded in 1935 and approximate capacity of new equipment shipped in 1936.

Black columns represent the tonnage loaded with mechanical devices, including conveyors, in 1935. Capacity of new equipment shipped in 1936 is indicated by white extensions at top of columns.

The increase indicated for West Virginia is continuing into 1937. In April 1937 the report of the State department indicated that 12.6 percent of the State output was loaded with conveyors or loaders compared with 2.1 percent as late as 1935.

The data so far available to the authors are not sufficient to permit an estimate of the total tonnage mechanically loaded in the bituminous-coal industry in 1936. Eugene McAuliffe has recently stated, "When 1936 figures are made available * * * a possible total of 60,000,000 tons may be shown."¹²

Reports to the Pennsylvania Department of Mines indicate a total of 11,019,235 tons of anthracite loaded mechanically in 1936 as against 9,279,057 tons reported to the Bureau in 1935.

¹¹ Allowances for capacity sold in 1936 are based upon the reported number of machines sold during the year and the average tonnage loaded by machines of similar type in 1935, as shown by detailed reports of mine operators to the Bureau of Mines.

¹² Mining and Metallurgy, January 1937, p. 37.

REGIONAL DISTRIBUTION OF MACHINES, BY TYPES

The maps in figures 17 to 20 are designed to bring out the striking differences in the regional distribution of the principal types of loading machinery over the coal fields of the country. Differences in seam conditions have led to the selection of equipment considered by the operator best suited to local needs. The existing distribution of equipment is affected further by the past variations in wage scales already cited and by the dates at which the equipment was installed. Operators who invested in one type of equipment in 1927 might choose a different type in 1937. It is recognized that machines successful in one area may fail in another, and the problem of selection is the subject of active discussion. Improvements in design and in operating practice are adapting mobile loaders to conditions formerly thought suited only to conveyors and vice versa, and the future distribution of equipment may differ widely from that of today.

Mobile loading machines.—Figure 17 shows the location of mobile loading machines that had been installed underground in coal mines down to January 1, 1937. It includes all machines reported as in use by mine operators during 1935 plus the shipments reported by manufacturers in 1936. The map, therefore, gives a trustworthy picture of the regional distribution of mobile-type machines down to the beginning of 1937.

The map shows in outline the important coal-mining counties that produce 100,000 tons or more in a normal year. Each black dot represents four loaders (or major fraction of four), and the hollow circles represent counties in which there are one or two machines only. Counties left blank were using no machines of this type, so far as known, at the beginning of 1937.

Mobile loaders represent the largest unit investment and have the largest hourly capacity of the several types of machines. Where conditions favor their use mobile loaders therefore effect the largest saving in labor, and in 1935 they produced more bituminous coal than all other types of machines combined. The conditions favoring mobile loaders are thick seams, good roof, flat or gently dipping beds, and the absence of thick partings or bands of impurities in the seam. Naturally, these factors rarely exist in ideal combination, and mobile loaders have been successfully used in many localities under more difficult conditions. Various designs of mobile loaders are available to work seams as thin as 30 inches.

Machines of this type, however, have been used most widely in certain clearly marked areas. These include the thick beds of the Illinois-Indiana field; Carbon County, Utah; Carbon and Sheridan Counties, Wyoming; the Roundup field of Musselshell County, Mont.; and, within the last 2 years, the Pittsburgh bed in northern West Virginia and the Logan field of southern West Virginia. The Pittsburgh bed in Pennsylvania and eastern Ohio has been the scene of persistent and determined effort to adapt mobile loaders under difficult roof conditions; and considerable success has been attained, with promise of more hereafter.

An obstacle to the use of mobile loaders—and of other machines that eliminate hand shoveling entirely—is the presence of dirt bands or partings in the coal. Hand loading affords an opportunity to miners to reject the impurities as they shovel the coal. Loading machines cannot do this, and unless the problem can be handled by improve-

ments in face preparation, the partings being cut out before the face is shot, it may be necessary to install mechanical cleaning equipment on the surface at considerable expense. Many mines installing mobile loaders have therefore put in mechanical cleaners as well; and where the economies underground are large, the added expense in preparation has been readily absorbed. But in still other cases the cost of mechanical cleaning favors the selection of alternative types of underground equipment.

Duckbills.—Self-loading conveyors, of which those equipped with duckbills are by far the dominant type, combine virtual elimination of hand shoveling with the transport function of conveyors. Duckbills are therefore handicapped by partings or impurities in much the same way as are mobile loaders. Duckbills have found their greatest

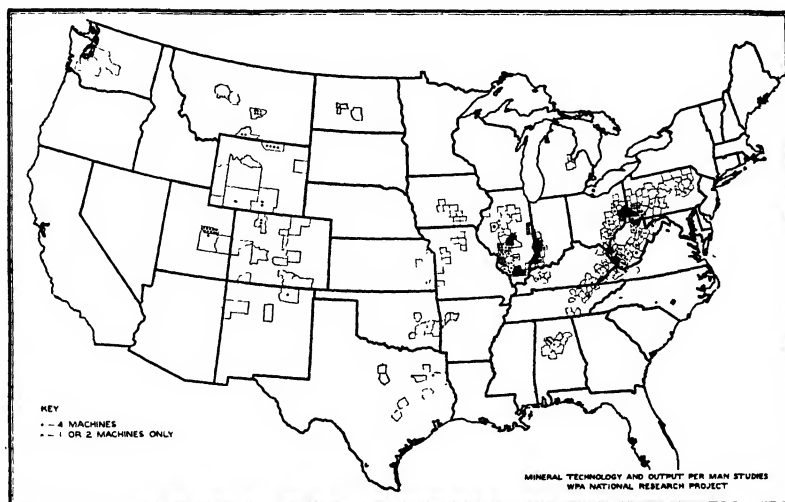

FIGURE 17.—Distribution of mobile loading machines installed underground in coal mines at the beginning of 1937.

The map shows in outline the counties producing 100,000 tons or more of coal in a normal year. Each black dot represents four mobile loading machines. Counties in which one or two machines only were installed are indicated by circles. Other counties were using no machines of this type in 1936, so far as known.

utility in areas where the seams pitch too steeply for the ready use of mobile-type machines, and many of the areas showing use of duckbills in figure 18 are characterized by moderate to steep dips. Duckbills have also been employed to advantage in thin seams especially adapted to conveyor mining and are used in this way in the anthracite and a number of the bituminous fields. In 1935, 30 machines were reported by operators in the anthracite region and 179 in the bituminous fields. Duckbill-equipped conveyors have been most widely employed in the mines of southern Wyoming, where these machines were invented and originally developed.

Scrapers.—Installations of scrapers are indicated in the same map (fig. 18) by the symbols X and Y. By far the greatest centers where scrapers are employed are the Northern and Western Middle anthracite fields, and in several counties of the anthracite region so many scrapers are used that the county appears on the map as solid black. In 1935, 507 scraper units were in active use in the anthracite region, and manufacturers reported sales of 9 additional units to this area

in 1936. However, the number of new installations is now small compared with the number of conveyors.

In the bituminous-coal fields scrapers have been retarded by two factors of little consequence in the anthracite region. Where the coal is friable scrapers may greatly increase degradation, and where the bottom is soft they may scour up dirt and increase the ash content of the product. Partly for these reasons the total number of scraper installations in the bituminous-coal fields has been declining since 1930.

Under certain conditions scrapers are used to advantage, particularly in narrow or long wall work, in thin or inclined beds. Among the centers of present use are Indiana County, Pa.; Walker County, Ala.; Colfax County, N. Mex.; and southern Wyoming.

In Arkansas and eastern Oklahoma a modification of the scraper idea, known as the scow, has been used with marked success in mining thin seams. Scows are more cousins than brothers of scrapers. They consist of a steel plate which is pushed into the kerf or undercut made with the cutting machine. The coal is then broken onto the scow and dragged to a loading platform. Scows, therefore, avoid the degradation and the mixing of bottom impurities with the coal which often handicap scrapers proper.

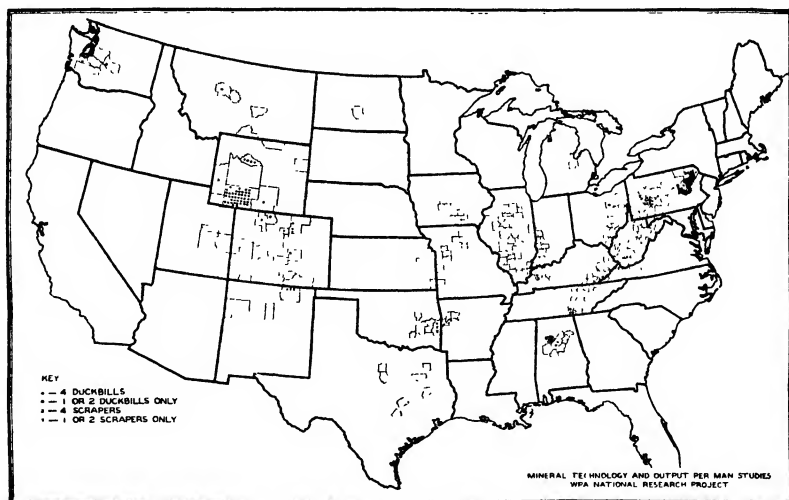

FIGURE 18.—Distribution of duckbill-equipped conveyors and of scrapers installed underground in coal mines at the beginning of 1937.

Pit-car loaders.—The period of greatest activity in the installation of pit-car loaders was 1927 to 1931. During that period great numbers of these machines were introduced in the mines of Illinois and Indiana and, to a smaller extent, in certain other fields. Pit-car loaders involved a much smaller investment and less modification of standard room-and-pillar practice than other types of loading machinery. Although the savings in labor were less than with mobile-type machines, at the wage scale then prevailing in the Middle West pit-car loaders permitted a definite reduction in cost. In late years few new machines of this type have been sold. Large numbers remain in use, however (fig. 19). The centers of greatest activity are the Belleville and Central Illinois fields; the Southern Illinois field; the Danville district of

Illinois; Indiana; the Pittsburgh bed in Pennsylvania; and St. Clair and Jefferson Counties, Ala.

Pit-car loaders, however, appear in smaller numbers in some other fields of the country, and there are undoubtedly possibilities for their successful application.

Face conveyors.—Figure 20 shows the distribution of the hand-loaded conveyors installed underground down to the end of 1936. The figures include all types of conveyors—chain, shaker, or belt—except those equipped with duckbills, which have been previously shown in figure 18.

The number of conveyor installations has been increasing rapidly in both the anthracite and bituminous-coal fields. In the anthracite region conveyors have established themselves as the dominant type of loading machinery and in 1935 handled about 70 percent of the tonnage loaded with mechanical devices. In the bituminous-coal fields the conveyors have increased their share of the total tonnage mechanically loaded from 13.4 percent in 1928 to 16.3 in 1935.

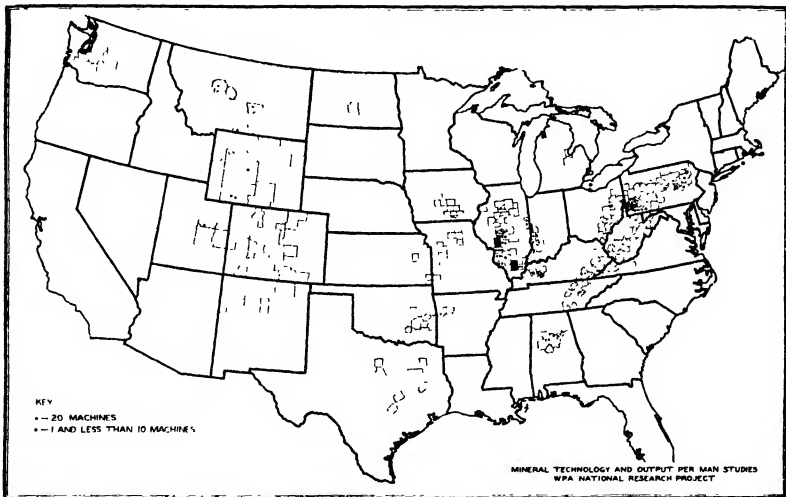

FIGURE 19.—Distribution of pit-car loaders installed underground in coal mines at the beginning of 1937.

Up to the present the labor savings effected with the use of conveyors have been much smaller, on the average, than with mobile-type machines. Conveyors do not eliminate hand shoveling, though they greatly reduce the labor by reducing the height to which miners must lift the coal and the distance to which they must cast it. Some recent conveyor installations, however, suggest that past performance is far from indicating their future potentialities.

Conveyors have been found applicable under certain conditions where mobile-type loaders are handicapped, and they are the type of machine most widely used in thin beds. Beds too thin to yield the concentration of tonnage that makes best use of the higher capacities of mobile loaders have been worked successfully with conveyors. Moreover, the conveyors perform a function of transport, and where, as sometimes happens, they eliminate expensive brushing of top or taking up of bottom to provide clearance for mine cars and mules or locomotives, they may effect substantial savings. Inclined seams are

no obstacle to conveyors of suitable design, and some dips too steep for application of mobile-type loaders have therefore been mechanized in this way.

A further advantage of conveyors is their adaptability to the working of seams containing partings or impurities. As the coal is shoveled onto conveyors by hand, opportunity is offered for hand-picking of refuse, much as with hand-loading proper. If necessary, inspectors can be stationed along the conveyor lines, and the car trimmer who tends the discharge end of the conveyor is universally instructed to watch for pieces of slate as the coal passes into the mine car. With these possibilities for hand cleaning, conveyors can be installed without material sacrifice of quality in a seam where the amount of impurities would necessitate installation of mechanical cleaning if the loading were mechanized with mobile-type machines.

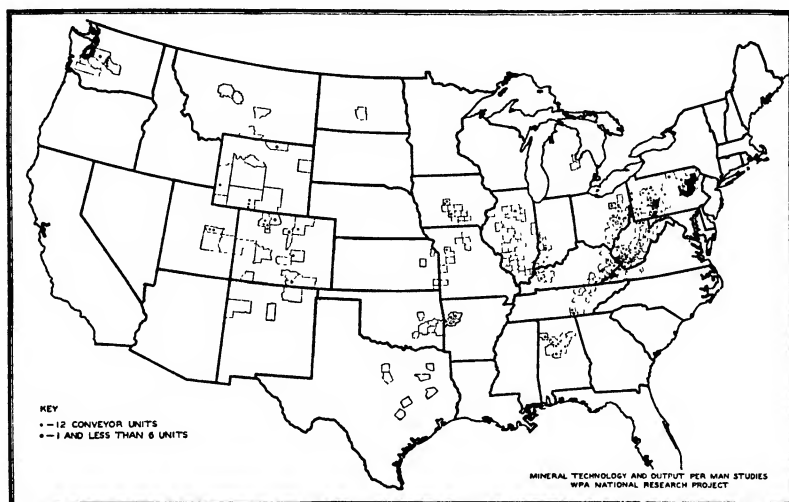

FIGURE 20.—Distribution of hand-loaded conveyors installed underground in coal mines at the beginning of 1937.

As might be expected from these considerations, conveyors are little used in the thick, flat seams of Illinois and Indiana, and, in general, the areas where the mobile loaders are most widely used have shown little interest in conveyors. The largest single field for conveyors has thus far been the Pennsylvania anthracite region, where there has been an extraordinary development in the use of such machines, particularly those of the shaker type. In the bituminous-coal fields the areas of greatest activity are the low-volatile districts of central Pennsylvania (especially Cambria, Somerset, and Indiana Counties), Alabama, Arkansas, southern Wyoming, and the Roslyn field of Washington. Within the last 2 years, the use of conveyors has spread rapidly in the Southern Appalachian region, and numerous installations are reported in both the low- and high-volatile districts. Western Pennsylvania, also, reports active interest in the possibilities of conveyor mining.

Combined installations.—The maps showing the present distribution of machines emphasize the fact that expert opinion regarding the selection of mechanical loading equipment is in a state of flux and

that new adaptations are likely to appear. One possible development which deserves watching is the combination of mobile loaders and conveyors in the same mine, a system that should yield economies both in loading and in transportation.

Sales, by regions, in 1936.—The location of sales of new equipment made in 1936 cannot be shown in detail without disclosure of the business of individual manufacturers. Insofar as the figures can be properly broken down, they are given in tables 28 and 29 of the section on Bituminous coal in the Coal chapter of the Yearbook.

MECHANICAL LOADING IN METAL AND NONMETAL MINES

By N. L. PLEIN, F. E. BERQUIST, AND F. G. TRYON

Mechanical loading with both scrapers and power shovels established itself underground in the metal mines even earlier than in coal mines, and there is an extensive technical literature on the problems of mining practice that it has raised. Up to the present, however, there have been no statistics to show either the number of machines or the tonnage of ore mechanically loaded.

The figures here presented are no more than a reconnaissance, designed to indicate the trends of mining practice in the application of loading machinery. If omissions are noted, the authors will welcome criticism or supplementary data that will make the record more complete.¹³

TONNAGES MINED UNDERGROUND AND THE FIELD OF MECHANIZATION

Some idea of the potential use of subsurface loading equipment may be gained by reviewing the tonnage of minerals now produced by underground mining in the United States. The metals and the nonmetals will be briefly considered.

Metallic ores.—Not counting the 71,000,000 tons won from open pits, which represent another phase of mechanization, the following table shows a total of more than 98,000,000 tons of ore produced from underground.

Tonnages of ore classified according to mining methods at metal mines producing \$100,000 or more in 1929

[Quoted from C. W. Wright, Mining Methods and Costs at Metal Mines of the United States: Inf. Circ. 6503, Bureau of Mines, 1931, p. 5. The 405 mines covered produce 95 percent of the total output of metallic ore. Figures in short tons]

Mining method	Gold ore, tons	Copper ore, tons	Silver, lead, and zinc ore, tons	Iron ore, tons	Total tons, ore	Percent of total tonnage of ore	Percent of total man-hours of labor
Underground:							
Square-set.....	379,022	4,318,294	3,121,746	-----	7,819,062	4.6	24.8

Grand total.....	6,401,798	64,501,947	21,299,748	77,765,873	169,969,366	100.0	100.0

¹³ The authors are indebted to Chas. F. Jackson, chief engineer, Mining Division, and E. W. Pehrson, Metal Economics Division of the Bureau of Mines; also to J. R. Thoenen, George C. Helkes, and H. P. Sweeney, of the Bureau, for field notes and criticism.

A review of the systems of mining used should give a rough idea of the outer limits of possible mechanization. That the limits are necessarily uncertain, any mining man will realize. No two mines are alike, and the statistical groupings conceal a great variety of conditions. Each mine in such a count has to be classified according to the dominant method employed, yet numerous mines utilize more than one method to meet local variation in conditions. Hence the same mine may profitably employ mechanical loading devices in one section and gravity or hand loading in another.

On the other hand, nearly all mines produce some ore from development work, and the marked savings in cost or increase in speed often obtained by mechanical loading in drifts and headings indicate that in the future all mines may load some ore mechanically.

It appears at once that most of the 7,800,000 tons mined with square-sets can hardly be machine loaded, either because of closeness of timbering or other factors. The most that can well be anticipated here is a gradual shift to other systems of mining, which in some instances may offer greater scope for mechanization.¹⁴

On the other hand, a much larger fraction of the total tonnage is mined by methods in which the work of loading into cars and even the movement of ore within the stopes is accomplished by gravity. Bituminous-coal engineers envy metal miners their opportunity to tunnel under the mineral and draw it out in this way, and it seems clear that no effort will be spared to make gravity do the work and that the proportion produced by block caving and by shrinkage will tend to increase, wherever the ore bodies are suited to those methods. Even here there may be room for auxiliary employment of loading machinery, as scrapers are used at Climax, Colo., in working a massive deposit adapted to shrinkage or caving.

This leaves the tonnages produced by open-stope, top-slicing, sub-level-caving (in the Lake Superior iron country), and cut-and-fill methods the principal candidates for mechanical loading. Indeed, in many mines using these methods the application of scrapers or power shovels is already far advanced.

The table, however, shows nothing of the large amount of country rock it is often necessary to handle either in accessory construction or in current development work. Recent experience emphasizes the savings of power loading in driving tunnels or headings, whether in rock or ore. The aggregate tonnage involved is great, and it offers one of the principal fields for mechanical loading below ground.

Nonmetals.—Finally, it is necessary to reckon with the surprisingly large tonnage of nonmetallic minerals now obtained from underground workings. Some idea of the possibilities in this direction is given by the following table, which indicates a total of 18,528,000 tons of crude material taken from underground in the year 1929. Much of this is already mined mechanically, and still more is likely to be.

¹⁴ Wright, C. W., *Mining Methods and Costs at Metal Mines of the United States*: Inf. Circ. 6503, Bureau of Mines, 1931, pp. 32-33.

Approximate tonnage of the principal nonmetals produced by underground mining, 1929

[Wherever possible, figures represent the tonnage of crude material hoisted before beneficiation]

	<i>Short tons mined underground</i>		<i>Short tons mined underground</i>
Limestone ¹ -----	11, 108, 317	Fluorspar-----	130, 000
Gypsum-----	2, 708, 711	Phosphate rock (1935)---	113, 928
Rock salt-----	2, 113, 010	Miscellaneous nonmetals--	500, 000
Clay ¹ -----	786, 874		
Pyrites (1935)-----	566, 961		18, 527, 801
Potash (1935)-----	500, 000		

¹ Census of Mines and Quarries, 1929, pp. 369 and 393. The figures for clay represent only enterprises whose product was sold as clay and exclude mine operations of clay-products manufacturers. In addition, 432,866 tons of clay were mined by companies producing from both underground and surface workings at the same operation.

TOTAL NUMBER OF LOADING UNITS SOLD

Sales of scrapers and shovel loaders to operators of metal and non-metal mines in each year from 1923 to date are summarized in the table following:

Number of scraper loaders and shovel loaders sold for use underground in metal and nonmetal mines

[Figures represent sales to mines in the continental United States, not including exports or sales to contractors on construction projects. Subject to revision]

Year	Scraper loaders (hoists or complete units)	Shovel loaders	Year	Scraper loaders (hoists or complete units)	Shovel loaders
1923-----	254	57	1931-----	126	2
1924-----	341	18	1932-----	104	14
1925-----	373	15	1933-----	62	12
1926-----	284	36	1934-----	67	23
1927-----	414	39	1935-----	135	44
1928-----	363	32	1936-----	249	70
1929-----	645	35			
1930-----	335	22		3, 752	419

This information is based primarily upon reports from 11 manufacturers of shovels and 8 manufacturers of scrapers and scraper hoists. Direct reports could not be obtained on one make of shovel no longer actively produced, and one manufacturer of hoists had not reported when the books were closed. To round out the figures, an estimate has been included in these two cases, derived from lists of installations furnished by State mine inspectors and by correspondents in the field.

The following manufacturers of mechanical loading equipment have cooperated for the purpose of this inventory:

Manufacturers of underground scraper loaders or hoists

Sullivan Machinery Co., Chicago, Ill.
 Gardner-Denver Co., Quincy, Ill.
 Lake Shore Engine Works, Marquette, Mich.
 Goodman Manufacturing Co., Chicago, Ill.
 Vulcan Iron Works Co., Denver, Colo.
 Vulcan Iron Works, Wilkes-Barre, Pa.
 Lidgerwood Manufacturing Co., Elizabeth, N. J.
 Sauerman Bros., Chicago, Ill.

Manufacturers of underground shovel loaders

The Eimco Corporation, Salt Lake City, Utah; Eimco-Finlay loader.
 Gardner-Denver Co., Quincy, Ill.; Gardner-Denver loader.
 Nordberg Manufacturing Co., Milwaukee, Wis.; Nordberg-Butler shovel.
 Goodman Manufacturing Co., Chicago, Ill. (with St. Louis Power Shovel Co.);
 Conway and Goodman power shovels.
 The Thew Shovel Co., Loraine, Ohio; Thew and St. Joe type shovels.
 The Marion Steam Shovel Co., Marion, Ohio; Marion shovel.

The total number of machines sold to metal and nonmetal mines during the 14-year period from 1923 to 1936 is placed at 419 shovel loaders and 3,752 scrapers. These figures undoubtedly include many experimental installations, which were sometimes only partly successful and sometimes even abandoned. In coal mining, for instance, there are records of 459 mines which at one time or another have tried mechanical loading without adopting it as standard practice, at least down to the end of 1936. Difficulties in the design of machines, in local seam conditions, and in adaptation of mining methods have combined with market and wage-rate factors to delay wider use of coal loaders. A similar record of trial and error has undoubtedly occurred in the metal mines.¹⁵ These cases of partial success or failure are no more than enough to suggest the need of careful study of local conditions and comparison of the alternative types of equipment available before making the investment in loading machinery.

SCRAPER LOADERS

Details of the early installations of scrapers underground will be found in a monograph by C. E. van Barneveld on mechanical loading in metal mines.¹⁶ Figure 21 picks up the trail where van Barneveld left it in 1923. By that time scraper loading was going forward with a rush. The pioneer installations in the Michigan copper mines and the Lake Superior iron ranges in 1915-17 and in the Tri-State area in 1919 had proved the possibilities of scrapers at a time when shortage of manpower and rising wages focused the attention of managers upon labor-saving devices.¹⁷ In the post-war years, declining prices both of iron and the nonferrous metals further stimulated the search for cost reduction. Throughout the period from 1923 to 1929, sales of scraper equipment continued in large volume. Indicative of the savings effected is the record of Gogebic County, Mich., where the output of iron ore per miner per day is reported to have increased from 2.91 tons in 1923 to 5.96 in 1929.¹⁸

By far the largest number of machines went to the iron country of Michigan and Minnesota and to a smaller extent Alabama, the peak in number sold being reached in 1929. The great depression fell with exceptional severity on the iron industry, and sales of equipment

dropped by 1933 to a small fraction of the former level. Recovery of business sent the curve of sales upward, and there were further increases in 1935 and 1936. Were it possible to represent the capacity of the equipment rather than the number of units, the sales in 1936 would appear substantially higher, for meanwhile there has been a marked increase in size of typical scraper hoists. In 1923, 4- to 7½-horsepower hoists were the rule; now they range up to 150 horsepower and use much heavier equipment and larger scrapers.

FIGURE 21.—Shipments of scraper loaders for use underground in metal or non metal mines, 1923-36. Note that the figures represent number of units only without regard to capacity. Were it possible to allow for the large increase in the size of machines during this period, the sales in recent years would look proportionately larger. Based upon detailed reports from eight manufacturers, with an estimate for one company not heard from when the books were closed.

As scraper mining has become the established practice in the Lake Superior iron mines, wherever it is applicable,¹⁹ future installations in this area will hardly equal those of the 1920's, when the mines were being initially equipped. It is evident, however, that a substantial demand for this type of equipment will continue to be found in replacements and in retirement of obsolete machines. In the Alabama iron mines, scrapers have been widely²⁰ used, but a considerable part of the district output is still loaded by hand.

In nonferrous-metal mining, one of the largest single fields for the use of scrapers until recently has been the Michigan copper mines. Along with power drilling, concentration of haulage, and selective mining, the use of scraper loading has been one of the principal economies that have enabled the Michigan mines to combat the difficulties of increasing depth and to survive in the competitive struggle.²¹

Purchases of scrapers by nonferrous and precious metal mines reached a peak about 1924 and for some years thereafter declined. Beginning in 1935, however, there was a sudden pick-up, apparently forecasting further activity in this field. A notable feature of the last 2 years has been the increase in sales to precious-metal mines, reflecting the boom in gold production that followed devaluation of the dollar.

The growth of scraper loading in metal mines is in contrast to the experience of coal mines. Numerous coal mines—both bituminous and anthracite—working thin or pitching seams have tried scrapers, and some 3,800,000 tons of coal are loaded in this way. But in coal

FIGURE 22.—Shipments of shovel loaders for use underground in metal or nonmetal mines, 1923-36. Based upon detailed reports from 11 manufacturers. Includes estimates for 1 make of machines not now produced.

mines the scraper may often gather up dirt as it drags along the floor, thereby increasing the ash content of the product; and it also increases breakage and reduces the proportion of the profitable domestic sizes. In metal mining, these considerations do not apply.

Nonmetallic mining, like coal, has made less use of scrapers than of shovel loaders underground.

SHOVEL LOADERS

Installations of shovel (or mobile-type) loaders during the same period are shown in figure 22. The record for shovel loaders covers two distinct types of equipment. From 1923 to 1931 the machines sold consisted chiefly of comparatively large units designed for loading in open chambers or stopes. Beginning about 1932, the record is dominated by the sale of smaller-type machines designed primarily for loading in headings or tunnels. Machines of both kinds have been sold in both periods, but there has been a definite shift of emphasis.

Marked activity in the use of power shovels of the first type had occurred before the diagram begins. The largest number of machines

had gone into the southeast Missouri disseminated-lead mines. Favorable conditions and progressive management in that field have given it a preeminence in the use of power shovels underground.

The first experiment with a power shovel in the district was made in 1912, but the abundance of hand shovelers and the low rate of wages then prevailing were found to yield little incentive to mechanize at that time.²² The World War, however, stimulated a reconsideration of mechanical loading. The munitions demand, coinciding with the shortage of labor, led to the reintroduction of machines in 1917. Improved machines were developed, adapted to the conditions underground, and by November 1923 a total of 55 power shovels was in use in the field.²³ Since then installation of machines has continued at less rapid rate, and steady advances have been made in the efficiency of operation. In this area mechanical loading has now replaced hand shoveling entirely, except for incidental clean-up. An indication of the saving in labor effected is found in the report that in one mine of southeast Missouri machine mucking requires 0.061 man-hour per ton and hand mucking 0.416 man-hour per ton.²⁴

Power shovels of the larger types were purchased by a number of other metal mines. They were also the predominant type of equipment installed for underground loading in nonmetallic mineral mines. Sales of the larger types of shovels continued through the great depression, though naturally on a diminished scale.

The last 5 years, however, have witnessed a remarkable activity in the use of smaller shovels of the second type, designed especially for driving tunnels and headings, either in rock or in the vein. Machines for such development work had appeared upon the market during and just after the war²⁵ but achieved no general acceptance. Recent improvements seem to have overcome earlier difficulties, and the greater part of the shovels sold from 1934 to 1936 consists of such smaller machines. As the curves in figure 22 represent the number of machines only, without regard to size, the increase indicated is somewhat greater than would appear if figures on daily capacity were available.

The curves as plotted include domestic sales only. In addition, both scrapers and shovel loaders are shipped abroad. In the last 3 years there have been substantial exports, particularly of small tunneling shovels.

CONVEYORS

In 1935, more than 6,600,000 tons of anthracite and 10,285,309 tons of bituminous coal were loaded with conveyors, chiefly of the shaker type, but thus far conveyors are little used in other mines. However, the manufacturers reporting in this survey indicate that a few conveyors have gone into both metal and nonmetal mines. Belt conveyors are used as part of the transportation system at the Butler Bros. iron mine in Minnesota.²⁶ The Morton Salt Co. at Grand Saline, Tex., uses scrapers to load shaking conveyors in the rooms. The conveyors then carry the salt to the main entry where other conveyors of the belt type carry it to the shaft. No cars are used in this mine.²⁷ It is also reported that shaker conveyors are being tried in

the bedded iron ores of Lorraine.²⁸ These devices appear to have distinct possibilities in mining flat beds of the less abrasive materials.

FIELD DISTRIBUTION OF INSTALLATIONS OF LOADING MACHINERY

Figures 23 to 25 have been prepared to indicate the wide distribution of mechanical loading equipment underground.

Iron mines.—Figure 23 shows the localities where scrapers or shovel loaders have been introduced into the iron mines. Each circle represents an area where scrapers have been installed below ground, according to the manufacturers' records, in the period from 1923 to 1936. The number of circles is far from showing the total number of units sold and may give a mistaken impression of the relative importance of the different areas unless it is remembered that one dot standing for a single large area purchasing scores of machines may represent more than numerous scattered dots in areas of smaller production.

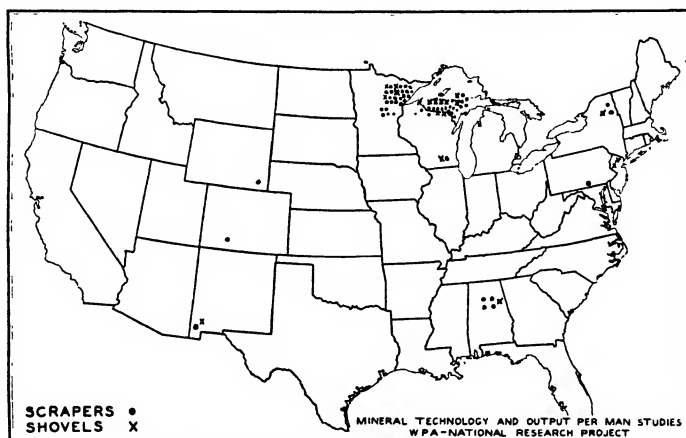

FIGURE 23.—Localities in which scraper and shovel loaders have been introduced underground in iron ore mines.

Each circle or X indicates a locality in which loading equipment of one make or another [was installed during the period from 1923 to 1936. Doubtless not all of the localities indicated are actively using the equipment at the present time.

In the same way, each cross mark in figure 23 represents an iron-mining locality where one or more power shovels were sold. It should be noted that a considerable number of earlier types had been installed before 1923. Were these machines included in the map, the number of iron-producing localities making use of shovel loaders would appear larger.

The map, however, emphasizes the fact that in iron mines the scraper has been the dominant type of mechanical equipment used in underground loading. It demonstrates also that purchases of loading machinery have been made in virtually every iron-mining district of the country, though some of the installations were experimental and doubtless not all of them are in active use today.

Nonferrous-metal mines.—Figure 24 illustrates in the same way the widespread interest in mechanical loading in the mines producing nonferrous and precious metals. Nearly every district of major im-

²⁸ Jacob, Louis, Transporting Iron Ore by Electrically Driven Shaker Conveyors at the Ottange 2 Pit, Moselle, France: Trans. 7th Session, Internat. Cong. Mining, Metallurgy, and Applied Geology, Paris, 1935.

portance has purchased at least some units of scraper or shovel equipment. No attempt is made to indicate the relative number of units; hence the southeast Missouri lead district, now 100 percent mechanized, is not much more conspicuous on the map than the Tri-State area, in which the number of installations has been small.²⁹ These two districts, lying side by side, illustrate how largely the factors of size of operation and character of deposit affect the utilization of machinery. In the Tri-State area, the less regular character of the mineralization and of the underground workings, smaller holdings, prevalence of the leasing system, use of small "cans" instead of large capacity cars in haulage, and other factors have worked to favor hand loading. Nevertheless, adaptation of power loading to the conditions of this district also would appear largely a matter of time.

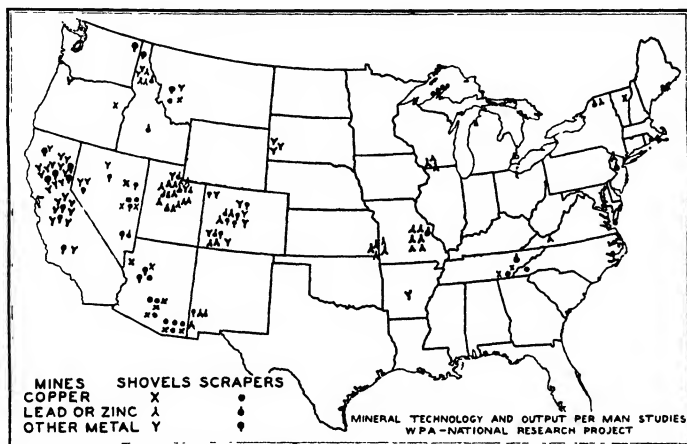

FIGURE 24.—Localities in which scraper and shovel loaders have been introduced underground in nonferrous metal mines.

As each symbol represents a locality installing machinery, the map gives no direct indication of relative importance in number of units sold. Thus the southeast Missouri lead district purchased scores of machines, whereas the adjacent Tri-State area has installed but few.

The conspicuous feature of the map is the large number of localities that have made use of loading machinery in the metal mining districts of the West. Every important metal is represented in the list—gold and silver, copper, lead and zinc, bauxite, manganese, vanadium, and molybdenum. Both scrapers and shovels are widely represented, and there are signs of rivalry between the two both for mucking in stopes and for development work.

The predominant consideration underlying the introduction of machines is one of cost. In some areas the item of cost alone is now reinforced by the increasing temperatures attendant upon depth. Magma, Bisbee, and some of the hotter workings at Butte are examples that might be cited of mines where the rock temperatures now encountered make the arduous labor of hand shoveling increasingly difficult or impossible.

Nonmetals.—As shown by figure 25, the distribution of loading equipment in nonmetal mines is largely concentrated in the Mississippi Valley and the East. The types of equipment chiefly used are power shovels or smaller mobile-type loaders, though scrapers also are widely

²⁹ Anderson, C. N., *Mining Methods and Costs at the Interstate Zinc & Lead Co.'s Hartley Mine, Tri-State District*: Inf. Circ. 6656, Bureau of Mines, 1932, p. 8.

distributed. The industries making greatest use of such equipment are underground limestone mining and rock salt.³⁰ Metal miners are not always aware that the production of limestone underground has grown from 1,670,000 tons in 1912 to 11,100,000³¹ in the active year 1929. Some of this production is obtained from steeply pitching beds by shrinkage methods and gravity loading,³² but the greater part is loaded with underground power shovels. Loading machinery has also been used, sometimes experimentally, in the underground mining of fireclay,³³ silica rock, glass sand, building sand, gypsum, phosphate rock,³⁴ ocher, pyrites, rock asphalt, fluorspar, and diatomaceous silica rock. Its most recent application is in the mining of potash in the newly developing industry at Carlsbad, N. Mex., where 98 percent of the production is produced with loading machines and scrapers.³⁵

The trends in mining practice suggested by the sales of equipment indicate an active interest among mining engineers in the problems of mechanization and point to the need for studies of operating experi-

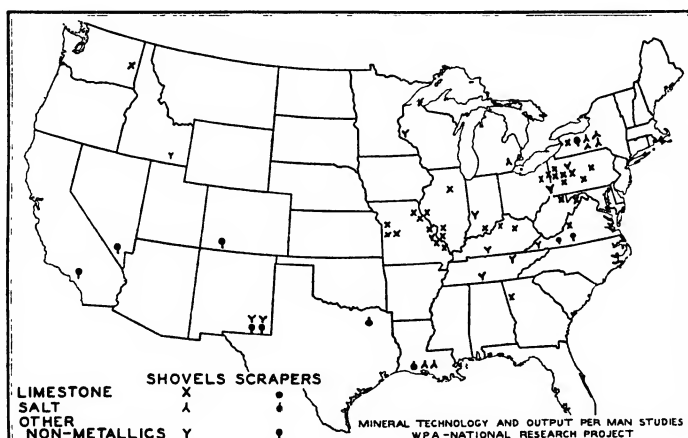

FIGURE 25.—Localities in which shovels and scraper loaders have been introduced in mining nonmetals underground.

In nonmetal mining the industries making greatest use of mechanical loading are limestone, salt, and potash.

ence in the application of machines under the widely varying conditions faced by practical miners. More time studies of mechanical loading are needed, especially loading in development work. The essence of all operating studies is adaptation to local conditions. The mass experience recorded in statistics is never a substitute for such individual analysis, but it may furnish a useful background. With the hope of providing such a background, the Bureau of Mines is adding to its annual reports of mine operation inquiries regarding the number and type of machines used and of the tonnage mechanically handled. A continuing analysis of the factors of mechanical equipment, mining practice, and man-hours per ton will, it is hoped, throw light on the current trends of mineral technology.

STATISTICAL SUMMARY OF MINERAL PRODUCTION

(GENERAL UNITED STATES SUMMARY AND DETAILED PRODUCTION BY STATES)

By M. B. CLARK

SUMMARY OUTLINE

	Page		Page
Introduction.....	53	General tables.....	55
Unit of measurement.....	53	State tables.....	66
Elimination of duplication.....	53		

INTRODUCTION

This report continues the series of annual statistical summaries published in previous years as chapters of Mineral Resources and of Statistical Appendix to Minerals Yearbook.

Review of the Mineral Industry, the first chapter of this volume, discusses the salient features of the mineral industry and various industrial and economic factors affecting it.

UNIT OF MEASUREMENT

The unit of measurement used by the Bureau of Mines for each mineral product in reports on the mineral resources is that common to the industry concerned, and the variation in these units makes it impracticable, if not impossible, directly to combine and compare the different minerals except as to value. Although most of the products are measured by weight, some are measured by volume, some by number of "pieces", etc., and for some no total quantity figures are available.

ELIMINATION OF DUPLICATION

In the totals for the United States, shown in the following "general" tables, duplication has been eliminated wherever practicable, and in the State totals given in the State tables virtually all duplication has been eliminated. For instance, in both general and State tables the output of coke is shown but its value is not included in the totals, as the value of the coal used in its manufacture enters into the value of the coal production which is included in the totals. For clay, the value of the products of the clay industries is included in both general and State totals as representing the first marketable form of the greater part of the clay produced; the quantity and value of the clay mined and sold in the raw state by miners to users of clay are shown separately also, but the value is not included in the totals as it is duplicated largely in that for clay products. No figures are available for total clay produced. For asphalt, both native and oil are shown in the gen-

eral tables, but the value of the oil asphalt is excluded from the totals as it duplicates that of the petroleum from which it is manufactured.

United States totals.—In the general tables both iron ore and pig iron are shown, but the value of the pig iron rather than the iron ore is included in the United States totals, as that is considered the better means of presenting the statistics for iron in its first marketable form. For gold, silver, copper, lead, and zinc the value of "smelter output" is included in the general totals, and to account more fully for the value of the ores treated these smelter figures are supplemented by the value of the byproduct sulphuric acid. The value of pigments (white lead, red lead, lithopone, litharge, and orange mineral) manufactured from metals is not included in the general tables, as the base from which they are made is included in the output of lead or zinc, whereas the value of sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide is included, as these are made in large part direct from the ores and do not enter into the lead or zinc totals, which represent smelter output.

State totals.—In the State tables also iron ore and pig iron are both shown. As blast-furnace products cannot be traced to the States in which the ore is mined, the value of the ore is used in the State totals. For ores of gold, silver, copper, lead, and zinc no values are shown, and in fact none are recorded; instead, for each of these metals the recoverable content of the ores is used as the basis of valuation. The value of the zinc and lead pigments is not included in the State total, as the recoverable zinc and lead content of the ores from which the products were made is included under zinc or lead. The value of the sulphuric acid produced as a byproduct of copper and zinc smelting and zinc roasting is not included in the State total, as tracing this product back to the State producing the ore has not been possible.

GENERAL TABLES

Mineral products of the United States, 1934-86¹

Product	1934		1935		1936	
	Quantity	Value	Quantity	Value	Quantity	Value
METALLIC						
Aluminum.....	74,177,000	\$14,094,000	119,295,000	\$22,070,000	224,929,000	\$41,612,000

Tin (metallic equivalent).....		(³)		(³)		(³)

¹ In this general statement certain of the figures represent shipments rather than quantity mined, and some of the figures for 1936 are subject to revision. For details see following chapters of this volume.

² Figures represent antimonial lead produced at primary refineries from both domestic and foreign primary and secondary sources; no figures for value of antimonial lead available.

³ Estimate of value of primary antimony and lead contents of antimonial lead from domestic sources included in total value of metallic products.

⁴ Largely from foreign ore; Bureau of Mines not at liberty to publish figures.

⁵ Value not included in total value.

⁶ Value included in total value of metallic products; Bureau of Mines not at liberty to publish figures.

⁷ Product from domestic ores only.

⁸ According to Bureau of the Mint. Valued at \$35 per ounce.

⁹ Figures showing values not available.

¹⁰ Figures for 1936 not yet available.

¹¹ According to Bureau of the Mint.

Talc and ground soapstone ²³	short tons.....	575, 660	4, 227, 096	603, 627	4, 547, 709	1, 968, 820	35, 400, 000
Total value of nonmetallic products (approximate).....	do.....	138, 505	1, 448, 685	172, 710	1, 848, 055	211, 055	2, 309, 941
Total value of nonmetallic products.....			2, 770, 600, 000		2, 910, 900, 000		3, 496, 000, 000

¹⁷ Value included in total value of nonmetallic products. For details of production in fiscal years see chapter of this volume on Helium.

¹⁸ 1934: Figures include fine mica recovered as by-product in washing kaolin but do not include mica obtained by grinding mica schists; mica schists are included as "miscellaneous minerals" under last item ("unspecified"). 1935-36: Figures include mica recovered from kaolin and mica schists. See chapter of this volume on Mica.

¹⁹ Canvass discontinued after 1913. Value of iron ore sold for paint included under last item ("unspecified").

²⁰ Sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide.

²¹ Equivalent as K₂O.

²² Figures for soapstone used as dimension stone included in figures for stone.

²³ Figures not yet available; estimate of value included in total value of nonmetallic products.

⁴ Value not included in total value

⁵ Value included in total value of metallic products; Bureau of Mines not at liberty to publish figures.

⁶ Product from domestic ores only.

⁷ Figures obtained through cooperation with Bureau of the Census. Figures for 1936 not yet available; estimate of value included in total value of nonmetallic products.

⁸ Includes brown coal and lignite, and anthracite mined elsewhere than in Pennsylvania.

⁹ Figures represent tripoli only. Value of diatomite included in total value of nonmetallic products; Bureau of Mines not at liberty to publish figures.

¹⁰ No canvass. Estimate of value included in total value of nonmetallic products.

¹¹ Value included in total value of nonmetallic products; Bureau of Mines not at liberty to publish figures.

Mineral products of the United States, 1934-36—Continued

Product	1934		1935		1936	
	Quantity	Value	Quantity	Value	Quantity	Value
SUMMARY						
Total value of metallic products.....		\$540,300,000		\$723,800,000		\$1,064,000,000
Total value of nonmetallic products (exclusive of mineral fuels).....		537,200,000		580,900,000		786,700,000
Total value of mineral fuels.....		2,233,400,000		2,330,000,000		2,706,300,000
Total value of "unspecified" (metallic and nonmetallic) products (partly estimated) ¹⁴		\$14,500,000		\$15,300,000		\$122,000,000
Grand total approximate value of mineral products.....		3,325,400,000		3,650,000,000		4,582,000,000

¹⁴ Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.

1934: Bismuth, cadmium compounds, chats (\$518,110), flint lining for tube mills, iodine (\$342,957), iron ore sold for magnets, iron ore sold for paint (\$26,151), lithium minerals (\$20,980), new ingot magnesium, natural magnesium hydrate (brucite), natural magnesium salts (\$1,296,325), calcareous marl (\$22,236), greensand marl (\$208,278), micaceous minerals (mica schists and vermiculite) (\$123,796), molybdenum (\$4,502,000), pebbles for grinding, selenium, silica sand and sandstone (finely ground) (\$1,301,265), sodium salts (carbonates and sulphates) from natural sources (\$1,402,338), tantalum ore (\$968), tellurium, and an estimate of the value of miscellaneous mineral products for which statistics are not collected annually by the Bureau of Mines.

1935: Bismuth, cadmium compounds, chats (\$386,840), flint lining for tube mills, optical fluor spar (\$184), iodine (\$248,654), iron ore sold for paint (\$28,683), lithium minerals (\$26,834), new ingot magnesium, natural magnesium salts (\$1,286,804), calcareous marl (\$94,

653), greensand marl (\$219,749), micaceous minerals (vermiculite) (\$88,445), molybdenum (\$7,261,000), pebbles for grinding, selenium, silica sand and sandstone (finely ground) (\$1,554,300), sodium salts (carbonates and sulphates) from natural sources (\$1,448,946), tantalum ore (\$4,521), tellurium, and an estimate of the value of miscellaneous mineral products for which statistics are not collected annually by the Bureau of Mines.

1936: Bismuth, cadmium compounds (\$906,000), chats (\$666,000), flint lining for tube mills, iodine (\$212,625), iron ore sold for magnets, iron ore sold for paint (\$33,037), lithium minerals (\$25,273), new ingot magnesium, natural magnesium hydrate (brucite), natural magnesium salts (\$1,629,725), calcareous marl (\$38,082), greensand marl (\$177,885), micaceous minerals (vermiculite) (\$184,387), molybdenum (\$11,933,000), pebbles for grinding, selenium, silica sand and sandstone (finely ground) (\$2,146,464), sodium salts (carbonates and sulphates) from natural sources (\$1,442,923), tellurium, and an estimate of the value of miscellaneous mineral products for which statistics are not collected annually by the Bureau of Mines.

Value of mineral products of the United States, 1880-1936

Year	Metallic		Nonmetallic		Unspecified (metallic and nonmetallic)	Total	
	Value	Increase or decrease (percent)	Value	Increase or decrease (percent)		Value	Increase or decrease (percent)
1880.....	\$187,881,000	(¹)	\$173,582,000	(¹)	\$6,000,000	\$367,463,000	(¹)

Grand total.....	40,971,790,000	-----	97,501,262,000	-----	225,137,000	138,698,189,000	-----

¹ Figures for earlier years not available.² Subject to revision.

The sum of the following State totals does not reach the total for the United States given in the preceding table partly because figures for certain of the products included in the United States total are not available by States of origin. This fact is brought out in the opening text of this chapter and in the second table following.

In addition, there are many factors (the more important discussed in the opening text) that account for the disagreement between the sum of the State totals and the grand total for the United States, by products. Chief among these are: (1) The use of iron ore values in State totals and pig iron values in United States total; (2) the use of mine figures for gold, silver, copper, lead, and zinc in the State totals and mint and smelter figures (supplemented by the value of byproduct sulphuric acid from copper and zinc smelting and zinc roasting and the value of zinc and lead pigments made in large part direct from ores) in the United States total; and (3) the inclusion of estimates in the United States total for a few products for which no canvass has been conducted for many years and for which no estimate by States is made.

Many other less important differences are involved, but both State and United States totals are as complete and definite as seems possible with the data available. The practice is consistent from year to year, and it is believed that the reader can determine readily just what minerals are covered by the total concerned.

In every table each mineral produced is listed, and all figures are shown except those that the Bureau of Mines is not at liberty to publish.

Value of mineral products of the United States, 1931-35, by States¹

State	1931	1932	1933	1934	1935
Alabama	\$38,506,558	\$19,170,152	\$23,291,204	\$29,827,048	\$31,772,042

¹ In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis. State totals for 1936 not yet available.

Mineral products of the United States and principal producing States in 1935

Rank in value	Product	Principal producing States	
		In order of quantity	In order of value
20	Aluminum.....	New York, Tennessee, North Carolina.....	Rank same as for quantity.
(*)	Antimonial lead.....	Not separable by States.....	Not separable by States.
51	Antimony ore.....	Idaho, Nevada.....	Rank same as for quantity.
58	Arsenic oxide.....	Montana, Utah, Idaho.....	Do.
63	Asbestos.....	Vermont, Arizona, Montana, Maryland.....	Vermont, Arizona, Maryland, Montana.
37	Asphalt:.....	Oklahoma, Texas, Kentucky, Alabama.....	Utah, Kentucky, Oklahoma, Texas.
19	Native.....	Not separable by States.....	Not separable by States.
49	Oil.....	Missouri, California, Georgia, Tennessee.....	Missouri, Georgia, California, Tennessee.
43	Barite (crude).....	Arkansas, Alabama, Georgia.....	Rank same as for quantity.
54	Bauxite.....	Not separable by States.....	Not separable by States.
30	Bismuth.....	California.....	Rank same as for quantity.
29	Borates.....	Wisconsin, Pennsylvania, West Virginia, Oregon.....	Wisconsin, Pennsylvania, Oregon, West Virginia.
34	Bromine.....	Michigan, North Carolina, California, West Virginia.....	Rank same as for quantity.
35	Cadmium (metal and compounds).....	Not separable by States.....	Not separable by States.
51	Calcium-magnesium chloride.....	Michigan, West Virginia, Ohio, California.....	Rank same as for quantity.
8	Cement.....	Pennsylvania, California, New York, Michigan.....	Pennsylvania, California, New York, Texas.
61	Chats.....	Missouri, Oklahoma, Kansas.....	Rank same as for quantity.
86	Chromite.....	California.....	Do.
6	Clay:.....	Pennsylvania, Georgia, Ohio, Missouri.....	Ohio, Pennsylvania, West Virginia, New Jersey.
26	Raw.....	West Virginia, Pennsylvania, Illinois, Kentucky.....	Georgia, Pennsylvania, Missouri, South Carolina.
2	Coal:.....	Pennsylvania.....	Pennsylvania, West Virginia, Illinois, Kentucky.
5	Bituminous.....	Pennsylvania, Ohio, New York, Indiana.....	Rank same as for quantity.
12	Coke.....	Arizona, Montana, Utah, Nevada.....	Pennsylvania, Indiana, New York, Ohio.
45	Diatomite.....	California, Oregon, New Jersey, New York.....	Rank same as for quantity.
89	Emery.....	New York.....	California, New Jersey, Oregon, New York.
52	Feldspar (crude).....	North Carolina, Colorado, South Dakota, Maine.....	Rank same as for quantity.
14	Flint lining for tube mills.....	Pennsylvania, New York, Ohio, West Virginia.....	North Carolina, New Hampshire, Maine, Virginia.
85	Fluorspar.....	Minnesota.....	Pennsylvania, New York, West Virginia, Ohio.
39	Fuller's earth.....	Kentucky, Illinois, Colorado, New Mexico.....	Do.
36	Garnet, abrasive.....	Georgia, Florida, Texas, Illinois.....	Florida, Georgia, Texas, Illinois.
64	Gems and precious stones.....	New York, New Hampshire.....	Rank same as for quantity.
(*)	Gold.....	No canvass for 1935.....	No canvass for 1935.
7	Graphite:.....	California, South Dakota, Alaska, Colorado.....	Rank same as for quantity.
84	Amorphous.....	Nevada.....	Do.
57	Crystalline.....	California, Montana.....	Do.
23	Grindstones and pulpstones.....	Ohio, West Virginia, Washington.....	Do.
74	Gypsum.....	New York, Michigan, Iowa, Texas.....	Do.
	Helium.....	Texas.....	Do.

65	Iodine (natural).....	California.....	Do.
Iron:			
10	Ore.....	Minnesota, Michigan, Alabama, Pennsylvania	Minnesota, Michigan, Alabama, Wisconsin.
4	Pig.....	Ohio, Pennsylvania, Illinois, Indiana	Pennsylvania, Ohio, Illinois, Indiana.
18	Kyanite.....	No figures available.	No figures available.
(9)	Lead.....	Missouri, Idaho, Utah, Oklahoma	Rank same as for quantity.
22	Lime.....	Ohio, Pennsylvania, Missouri, West Virginia	Do.
82	Lithium minerals.....	South Dakota	Do.
50	Magnesium.....	Washington, California	Do.
53	Magnesium.....	Michigan	Do.
47	Magnesium salts (natural)	Michigan, Oklahoma, California, Washington	Michigan, California, Oklahoma, Washington.
55	Manganese ore.....	Montana, Georgia, Arkansas, Virginia	Rank same as for quantity.
46	Manganiferous ore.....	Minnesota, Montana, Wisconsin, Michigan	Minnesota, Montana, Wisconsin, Georgia.
67	Manganiferous zinc residuum	New Jersey	Rank same as for quantity.
Mari:			
75	Calcareous.....	Wisconsin, West Virginia, Virginia, Minnesota	Wisconsin, West Virginia, Ohio, Virginia.
68	Greensand.....	New Jersey	Rank same as for quantity.
48	Mercury.....	California, Texas, Oregon, Arkansas	Do.
59	Mica.....	North Carolina, Georgia, New Mexico, Virginia	North Carolina, Connecticut, Georgia, New Mexico.
	Scrap.....	do	Rank same as for quantity.
	Sheet.....	North Carolina, Connecticut, New Hampshire, Colorado	Do.
76	Miscellaneous minerals (vermiculite)	Montana, Wyoming	Do.
83	Millstones.....	Pennsylvania, Ohio, Kansas, Indiana	New York, Virginia, North Carolina.
24	Mineral paints, zinc and lead pigments	No canvass for 1935.	Rank same as for quantity.
(6)	Mineral waters.....	Colorado, Arizona, New Mexico, Nevada	No canvass for 1935.
27	Molybdenum.....	Texas, California, Oklahoma, Louisiana	Rank same as for quantity.
3	Natural gas.....	California, Texas, Oklahoma, Louisiana	Texas, California, Louisiana, West Virginia.
11	Natural gasoline.....	California, Texas, Oklahoma, Louisiana	California, Texas, Oklahoma, West Virginia.
71	Nickel.....	Not separable by States.....	Not separable by States.
73	Oilstones, etc.....	Ohio, Vermont, Arkansas, Indiana	Arkansas, Ohio, Indiana, Vermont.
(9)	Ores (crude), etc.:		
	Copper.....	Utah, Arizona, Nevada, Michigan	Value not available.
	Copper-lead.....	Montana, Colorado, New Mexico, Nevada	Do.
	Dry and siliceous (gold and silver)	Alaska, California, Colorado, South Dakota	Do.
	Lead.....	Missouri, Idaho, Utah, Nevada	Do.
	Lead-zinc.....	Oklahoma, Kansas, Idaho, Utah	Do.
	Zinc.....	Oklahoma, Kansas, Tennessee, New Jersey	Do.
69	Peat.....	New York, New Jersey, Michigan, California	New Jersey, New York, Ohio, Florida.
88	Pebbles for grinding.....	Minnesota, California	Rank same as for quantity.
21	Petroleum.....	Texas, California, Oklahoma, Kansas	Texas, Oklahoma, California, Kansas.
25	Phosphate rock.....	Florida, Tennessee, Idaho, Montana	Do.
44	Platinum and allied metals	Alaska, California, Oregon, Nevada	California, New Mexico, Maryland, Wyoming.
31	Potassium salts.....	New Mexico, California, Maryland, Utah	Rank same as for quantity.
66	Pumice.....	Kansas, California, Nebraska, Oklahoma	Rank same as for quantity.
41	Pyrites.....	Tennessee, Virginia, Nebraska, New York	Do.
21	Salt.....	Michigan, New York, Ohio, Louisiana	Do.

Rank of States in metal production (except aluminum, ferro-alloys, and pig iron) arranged according to mine reports, not smelter output.

Separate figures for antimonial lead from primary sources not available.

No canvass for 1935.

No figures available.

Value not available.

Mineral products of the United States and principal producing States in 1935—Continued

Rank in value	Product	Principal producing States	
		In order of quantity	In order of value
13	Sand and gravel.....	New York, Illinois, Montana, California.....	New York, Pennsylvania, Illinois, California.
56	Sand-lime brick.....	New York, Michigan, Massachusetts, Minnesota.....	Rank same as for quantity.
60	Selenium.....	Not separable by States.....	Not separable by States.
72	Silica (quartz).....	Ohio, Missouri, New Jersey, Tennessee.....	New Jersey, Missouri, Ohio, Tennessee.
42	Silica sand and sandstone (finely ground).....	New Jersey, Illinois, Wisconsin, Pennsylvania.....	New Jersey, Illinois, Wisconsin, Ohio.
16	Silver.....	Idaho, Montana, Utah, Arizona.....	Rank same as for quantity.
33	Slata.....	California, Texas, Wyoming, Nevada.....	Pennsylvania, Vermont, New York, Maine.
28	Sodium salts (other than NaCl) from natural sources.....	California, Texas, Wyoming, Nevada.....	Rank same as for quantity.
9	Stone.....	Pennsylvania, Michigan, New York, Ohio.....	Pennsylvania, New York, Ohio, Michigan.
17	Sulphur.....	Texas, Louisiana, California, Utah.....	Rank same as for quantity.
32	Sulphuric acid from copper and zinc smelters and roasters.....	Pennsylvania, Illinois, Tennessee, Oklahoma.....	Do.
40	Talc and ground soapstone ⁶	New York, Vermont, California, North Carolina.....	Do.
87	Tantalum ore.....	South Dakota.....	Do.
80	Tellurium.....	Not separable by States.....	Not separable by States.
79	Tin.....	Alaska, South Dakota.....	Rank same as for quantity.
	Titanium ore:		
	Ilmenite.....	Virginia.....	Do.
77	Ilmenite.....	Virginia, Arkansas.....	Do.
70	Rutile.....	Missouri, Illinois, Arkansas, Oklahoma.....	Missouri, Illinois, Oklahoma, Arkansas.
62	Tripoli.....	Nevada, Arizona, Colorado, California.....	Nevada, Arizona, Colorado, Washington
38	Tungsten ore.....	Arizona, Colorado, Utah.....	Colorado, Utah, Arizona
78	Uranium and vanadium ores.....	Oklahoma, New Jersey, Montana, Kansas.....	Rank same as for quantity.
15	Zinc.....		

⁶ Exclusive of soapstone used as dimension stone (all from Virginia), which is included in figures for stone.

States and their principal mineral products in 1935 ¹

State	Rank	Principal mineral products in order of value
Alabama.....	21	Coal, iron ore, cement, clay products.
Alaska.....	30	Gold, copper, coal, platinum and allied metals.
Arizona.....	18	Copper, gold, silver, molybdenum.
Arkansas.....	31	Petroleum, coal, bauxite, natural gas.
California.....	3	Petroleum, natural gas, gold, natural gasoline.
Colorado.....	15	Coal, gold, molybdenum, silver.
Connecticut.....	43	Stone, clay products, sand and gravel, lime.
Delaware.....	50	Clay products, stone, sand and gravel.
District of Columbia.....	49	Clay products, stone.
Florida.....	34	Phosphate rock, stone, cement, fuller's earth.
Georgia.....	36	Stone, clay products, cement, fuller's earth.
Idaho.....	28	Silver, lead, gold, zinc.
Illinois.....	10	Coal, clay products, petroleum, cement.
Indiana.....	16	Coal, cement, clay products, stone.
Iowa.....	27	Coal, cement, gypsum, clay products.
Kansas.....	9	Petroleum, natural gas, coal, zinc.
Kentucky.....	8	Coal, natural gas, petroleum, clay products.
Louisiana.....	7	Petroleum, natural gas, sulphur, salt.
Maine.....	44	Stone, cement, clay products, sand and gravel.
Maryland.....	35	Coal, clay products, sand and gravel, cement.
Massachusetts.....	38	Stone, clay products, sand and gravel, lime.
Michigan.....	11	Iron ore, petroleum, cement, salt.
Minnesota.....	13	Iron ore, sand and gravel, cement, manganese ore.
Mississippi.....	42	Natural gas, clay products, sand and gravel, petroleum.
Missouri.....	19	Lead, clay products, coal, cement.
Montana.....	14	Copper, silver, petroleum, natural gas.
Nebraska.....	41	Cement, sand and gravel, clay products, stone.
Nevada.....	29	Gold, copper, silver, zinc.
New Hampshire.....	47	Clay products, stone, sand and gravel, feldspar.
New Jersey.....	24	Clay products, zinc, sand and gravel, stone.
New Mexico.....	20	Petroleum, natural gas, coal, potassium salts.
New York.....	12	Petroleum, stone, clay products, cement.
North Carolina.....	37	Clay products, stone, bromine, feldspar.
North Dakota.....	45	Coal, clay products, sand and gravel, stone.
Ohio.....	6	Clay products, coal, natural gas, petroleum.
Oklahoma.....	4	Petroleum, natural gas, natural gasoline, zinc.
Oregon.....	39	Gold, cement, stone, sand and gravel.
Pennsylvania.....	2	Coal, natural gas, petroleum, cement.
Rhode Island.....	48	Stone, sand and gravel, lime, clay products.
South Carolina.....	46	Stone, clay products, sand and gravel, gold.
South Dakota.....	26	Gold, sand and gravel, cement, stone.
Tennessee.....	25	Coal, cement, stone, phosphate rock.
Texas.....	1	Petroleum, natural gas, sulphur, natural gasoline.
Utah.....	17	Copper, silver, gold, coal.
Vermont.....	40	Stone, slate, talc, lime.
Virginia.....	22	Coal, stone, zinc, clay products.
Washington.....	32	Coal, stone, cement, sand and gravel.
West Virginia.....	5	Coal, natural gas, clay products, petroleum.
Wisconsin.....	33	Stone, clay products, sand and gravel, iron ore.
Wyoming.....	23	Petroleum, coal, natural gas, natural gasoline.

¹ In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis.

Prices of gold, silver, copper, lead, and zinc, 1932-36

Year	Gold ¹	Silver ²	Copper ³	Lead ⁴	Zinc ⁵
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1932.....	\$20.67+	\$0.282	\$0.063	\$0.030	\$0.030
1933.....	25.56	.350	.064	.037	.042
1934.....	34.95	\$.646+	.080	.037	.043

Miscellaneous 11.....		659,418		1,393,652
Total value, eliminating duplications.....		26,062,865		38,848,203

1 Value included under "Miscellaneous."

2 Figures obtained through cooperation with Bureau of the Census.

3 Value not included in total value for State.

4 No canvass.

5 Gold valued per ounce, as follows: 1934, \$34.95; 1935, \$35.

6 Reported as mica schist.

7 From ground mica schist.

8 Reported as scrap mica from ground mica schist.

9 Not valued as ore; value of recoverable metal content included under the metals.

10 From copper smelting.

11 Includes minerals indicated by "1" above.

International trade.....	103		

Continued increases in world production of most minerals during 1936 are less significant than the evidence of determined effort by many countries to achieve national self-sufficiency through the adoption or more vigorous application of measures restricting trade. The problem of insuring adequate supplies of mineral raw materials and its relationship to the achieving of economic self-sufficiency—the apparent goal of several major industrial countries—has not been solved as yet by exchange-control systems, barter transactions, import quotas, export restrictions, forced substitutions, and similar practices.

World production.—In 1936 the world production of industrial mineral raw materials approximated the peak output of 1928 and 1929; the production of a few minerals, notably crude petroleum, manganese ore, and aluminum, even surpassed that in the two peak years preceding the world depression. The acceleration of world production and distribution of industrial minerals from the low point of the world depression has been more noticeable in the 4 years beginning with 1933 than during the period immediately preceding the peak of 1929. Imports of key minerals by major consumer nations may be cited as indicative of continued annual increases in world production during 1936. In 1936 imports of virtually all minerals maintained at least the level of 1935 and, in a few instances, increased. For example, Germany's imports of bauxite increased 78 percent and of iron ore 33 percent; imports of iron ore into the United Kingdom increased 29 percent, of pig iron 185 percent, and of manganese ore 6 percent; and imports of iron ore into the United States increased 50 percent, of manganese ore 121 percent, and of pig tin 23 percent.

World consumption.—A major portion of the world output of mineral raw materials is consumed by relatively few countries, as the accompanying tables indicate.

In calculating apparent consumption by Japan, the production of Korea (Chosen), Formosa (Taiwan), and Sakhalin has been included; the consumption estimates for other countries do not include the output by colonial possessions.

Estimated annual average world production of principal mineral commodities, 1933-35, and percentage produced and consumed by 8 countries¹

³ Less than 0.5 percent.

Changes in world distribution.—Although world production and international trade in minerals have advanced rapidly since 1934 there have been more significant changes in regional distribution of world

output. Industrialization of many countries in southeastern and eastern Europe and South America, heretofore unimportant consumers of mineral raw materials, has progressed noticeably in recent years and has resulted in the adoption of certain protectionist policies to safeguard infant industries.

During 1936 the world was confronted with two conflicting methods of conducting international trade. Tariffs, which leave the promotion and development of foreign trade to the initiative of individuals, are recognized as one form of trade regulation or control. The reciprocal-trade-agreement program of the United States is an example; this program is based upon the Trade Agreements Act of June 12, 1934, and agreements with 14 countries resulted, of which 10 became effective in 1936, 3 in 1935, and 1 in 1934. The purpose of the trade-agreement program has been the expansion of foreign markets for surplus output through tariff adjustments. However, such agreements have been made largely because of the trade barriers and discriminatory practices of many foreign countries.

Contrasted with this method of promoting reciprocal trade are other forms of trade control and regulation now effective in many countries, the administration of which is also centralized in the national government. Such measures may be import quota restrictions, which tend to diminish or abolish trade with certain countries; import and export license requirements; exchange control systems, which are responsible for the adoption of "clearing" agreements limiting trade to the amount of foreign exchange available; and compensation or barter agreements. Exchange controls and regulations, effectively administered, enable the governments concerned to designate the countries with which their nationals may trade.

NATIONAL SELF-SUFFICIENCY OBJECTIVE OF EUROPEAN NATIONS

National policies in virtually all European countries—adopted largely since 1934 and applied most vigorously in 1936—have resulted in a change in the composition of foreign trade of these countries. Many such policies have been adopted to decrease the dependence of the major consumer nations on foreign sources for essential mineral raw materials. In certain instances, imports of raw materials have been reduced. However, the most noticeable effect of these policies has been diversion of the flow from major sources of supply, provided by nature with exportable surpluses, to secondary sources of supply with which the importing country has been able to negotiate trade-bargaining measures, the primary purpose of which is to increase exports of manufactured products.

A large percentage of world consumption of minerals is concentrated in central and western Europe, where dependence on imports for many such raw materials has resulted in drastic control measures. There was evidence in 1936 of more vigorous application of government decrees intended to reduce dependence on imports to a minimum yet assure adequate supplies to domestic industries through stimulated domestic production. In April 1936 the exportation of iron and steel products from Belgium was subjected to export licenses. In August 1936 the exportation of iron ore from France was prohibited, although exceptions to the prohibition were provided for under conditions established by the Minister of Finance. France likewise extended the prohibition against exportation, except under license, of scrap

lead, copper, tin, zinc, and nickel to include ingots derived from the melting of such scrap. Under revised regulations for the control of foreign trade during the third quarter of 1936, the list of products which could be imported into Italy only under a ministerial license without quota limitations included iron and steel structural forms, aluminum, antimony, nickel, and platinum. In April 1936 Italy likewise revised its regulations governing the importation of goods acquired through compensation or barter agreements which placed all commodities in seven groups, each group containing both import and export products. In general, export products can be compensated only against the import products listed in the same group, although provision is made for exceptions.

Germany.—From within its own confines Germany can provide supplies of coal and potash adequate to meet domestic requirements. However, from 1933 to 1935, 69 percent of its apparent consumption of iron ore, 100 percent of its consumption of manganese, and 52 percent of its apparent consumption of petroleum were imported. It also depends on imports for pig-iron requirements. Germany is the world's principal producer and consumer of aluminum metal, despite the fact that during the past 4 years more than 98 percent of the bauxite consumed was imported. Germany's industries depend on foreign sources of supply for all the minerals they require except coal and potash. The position of Germany as a major industrial nation, without adequate domestic reserves or colonial sources of essential raw materials, is unique, and because of its relative importance as a consumer of such products policies adopted during and prior to 1936, but more vigorously applied in 1936, deserve more than casual attention. Such national policies have had a definite influence on the trade relationships that now exist among other European countries, as well as on those between Germany and foreign countries.

Late in 1934 the German "Four-Year Plan" or "New Plan" was inaugurated. This plan is based on the premise that Germany should import no more than can be paid for. Germany's foreign trade with individual countries has varied greatly since then. Export trade with other European countries in the past enabled Germany to maintain purchases of raw materials in overseas markets. By 1934 the decrease in exports of finished products to other European countries resulted in adoption by Germany of purchase prohibitions and restrictions of foreign-exchange quotas. Ultimately the country became an importer of semifinished and finished products from western European countries, acquired through "clearing accounts", while imports of basic raw materials from abroad decreased materially owing to lack of exchange with countries capable of supplying essential raw materials. Since 1934 "clearing agreements" have been negotiated with virtually all southeastern European countries and several South American countries, as a result of which importation of raw materials from these areas has increased and imports from other European countries as well as other overseas sources of supply have decreased decidedly. Immediately prior to and during 1936 the trade relations between Germany and North American countries changed as a result of national policies adopted primarily to stimulate domestic production of essential raw materials, to reduce imports of such materials to a minimum, and to increase exports of finished products manufactured therefrom.

"Clearing account" transactions between Germany and other European countries have had a decided influence on the sources from

which essential raw materials have been obtained and the markets in which manufactured products have been distributed. By the end of 1936 Germany had "clearing agreements" with all European countries except Albania and Iceland. During 1936 Germany's foreign trade fluctuated considerably with countries with which a "clearing agreement" was in force. The accumulation of German exchange in many countries, attributed largely to the purchase of raw materials, resulted in restrictions by certain countries, especially the U. S. S. R. (Russia) and Yugoslavia, on exports of products to Germany to accelerate reduction of unfavorable trade balances. Germany's imports of manganese ore, which amounted to 394,256 metric tons in 1935, dropped more than 160,000 tons in 1936. This decline in tonnage, however, is less significant than the shift in countries of origin. In 1935 the U. S. S. R. (Russia) furnished 228,349 tons or 58 percent of Germany's imports compared with only 14 percent in 1936. In 1936, 47 percent of the manganese ore imported originated in the Union of South Africa and 22 percent in British India. The decline in German imports of Russian manganese ore is attributed to difficulties in trade relations that developed in 1936. These difficulties have also affected the trade in phosphate rock and petroleum. Negotiations between Germany and the U. S. S. R. (Russia) for the purchase of Russian manganese ore against certificates for German goods, or on the basis of compensation or barter trade, are reported to have been under consideration by the Soviet Union toward the end of 1936.

Compensation or barter trade between Germany and foreign countries in 1936 was largely controlled or regulated by the National Government. Prior to 1936 the Government, owing to the character of imports obtained on the basis of private barter, was confronted with the problem of ever-increasing imports of goods that were not considered absolutely indispensable to German industry. Likewise, it was found that in exchange for such goods imported, manufacturers and exporters were negotiating private-barter transactions involving German goods which could be sold abroad against available foreign exchange. This situation prompted the Foreign Exchange Board to issue new regulations, effective December 27, 1935, which definitely limited the character of goods that might be imported and exported on a private-barter basis. These regulations applied to German foreign trade generally, but they restricted trade more noticeably with North America, particularly the United States. They provide that only one-third of the value of German merchandise exported may be charged to private-barter accounts or agreements. The remaining two-thirds must be paid for by foreign buyers in reichsmarks or available foreign exchange. Special provisions in the decree cover goods that are classified as of vital importance to Germany.

International trade has been affected materially by exchange-control systems adopted in most central European countries, several South American countries, and certain southeastern European countries. The clearing agreements and compensation agreements in effect at present represent attempts to maintain an equilibrium in trade balances of countries that have adopted exchange-control systems.

The German policy of purchasing raw materials from countries that increase their imports of German manufactures has diverted the flow of mineral raw materials from sources that heretofore supplied a major portion of Germany's requirements to secondary sources of

supply that are of minor importance as industrial nations and depend on imports of semimanufactured and finished products. In 1935¹ there were 29 secondary sources of supply or entrepôts from which Germany purchased certain ores compared with 15 such markets in 1934; there were 6 primary markets in 1935 from which purchases of ores were negotiated by barter or clearing agreements compared with 4 in 1934. There were 57 primary markets from which Germany formerly purchased a greater portion of its essential imports of metals in 1935 at relatively low prices compared with 90 such markets in 1934. In two primary markets purchases were made by barter compared with one such market in 1934. There were 43 secondary markets or entrepôts in 1935 compared with 49 such markets in 1934. Of special significance are the increasing number of secondary sources or reexport markets from which Germany is apparently purchasing considerable essential raw materials and the consequent decrease in the number of primary sources of supply. During the 3-year period 1933 to 1935, inclusive, 84 percent of the primary copper consumed in Germany was imported, and 15 percent of the imports originated in the United States. During the first 11 months of 1936, 117,600 metric tons of primary copper were imported by Germany, but only about 5 percent is credited to the United States. Of significance is the increase in imports of copper from Yugoslavia, with which country Germany has a clearing agreement. According to the German press a shift in the purchase of raw materials during 1936 reflects the operation of the "Four-Year Plan" or "New Plan", which provides for the purchase of raw materials from countries that exhibit "increased willingness" to buy German manufactured products.

Germany's imports of bauxite also illustrate the effect of its trade policy. In 1929, France, the world's principal producer and exporter of bauxite, supplied Germany with about 40 percent of the tonnage imported, while Yugoslavia furnished only about 17 percent. In 1935 France contributed 15 percent, Yugoslavia 30 percent, Hungary 43 percent, and Italy 11 percent of Germany's total imports of bauxite. During the first 11 months of 1936 total imports of bauxite into Germany were 867,071 metric tons, an increase of approximately 78 percent over 1935. Of this total, France accounted for only 10 percent, Yugoslavia 21 percent, Hungary 34 percent, Italy 16 percent, and Netherland India 13 percent.

The German "Four-Year Plan", the objective of which is national economic self-sufficiency, has confronted domestic consumers of mineral raw materials with problems that require the active and constant assistance of the National Government for their solution. Copper and lead are produced in Germany but in quantities too small to meet requirements. Germany's reserves of bauxite are entirely inadequate; and its aluminum industry, which ranks first in the world, depends entirely on imports of the raw material. Although attention has been focused on technical processes for the recovery of aluminum from domestic clays, nevertheless the ability of Germany to use metallic aluminum as a substitute for other nonferrous metals is at present predicated on imports of commercial grades of bauxite. Substitutions have already been effected in the use of metals in Germany, and additional shifts are proposed under the "Four-Year Plan" which may decrease Germany's dependence on imports of

¹ Neue Wirtschaftsdienst, Folge 20, Sept. 6, 1935, p. 1217.

certain ores and metals. The cost factor of raw materials obtained from low-grade domestic deposits and through substitution is recognized as of secondary importance compared with the principal objective, national self-sufficiency. To further the latter a decree of the German Government, effective December 1, 1936, imposes an obligation upon owners of mining property to carry on prospecting and test-drilling operations when ordered to do so by the proper authorities. This law is regarded as a measure of the "Four-Year Plan" intended to force development of domestic mineral and metal production to the maximum point attainable, and it was enacted to overcome legal difficulties where there is an urgent national interest in development of mining properties whose owners remain inactive.

Germany has established boards of control which regulate the use and consumption of nonferrous metals, iron and steel products, and coal. These boards not only regulate and, in many instances, restrict the tonnage of ores and metals consumed by various industries, but also decide what ores and metals may be used or consumed. It is reported that in working out their regulations the boards consult specialists in the various lines of industry and that no specific prohibition is decreed without determining that a serviceable substitute material is available.

Southeastern Europe.—The countries of southeastern Europe, considered collectively, have a diversified and comparatively adequate supply of mineral raw materials with which to develop industrially. Lack of adequate private capital for expansion of industry is one of the most important problems in southeastern European countries; consequently the various governments have taken an active part in the development of domestic mineral reserves. Except for Rumanian petroleum, mineral raw materials of this area have been only partly developed. Yugoslavia, Bulgaria, and Rumania have the most important coal deposits in this region, while Greece depends on imports for her requirements. Rumania, which ranks fourth as a world producer of petroleum, exports about two-thirds of its annual output to countries other than those of southeastern Europe. Yugoslavia, now the most important producer of iron ore, is followed by Greece, and most of the production of these countries is exported. Hungary, although a producer of iron ore, depends on imports for its domestic requirements. Yugoslavia is now the second largest producer of copper ore in Europe. Yugoslavia and Greece are the principal European producers of chrome ore, except for the U. S. S. R. (Russia), while Bulgaria and Rumania are minor producers. Lead ore is produced in Yugoslavia, Rumania, Greece, and Czechoslovakia. Yugoslavia and Hungary follow France, the United States, and Italy as world producers of bauxite and have supplied the increased German requirements. Rumania also produces bauxite.

Despite the output of ores in this region, metal production in southeastern Europe is as yet little developed. Hungary, Rumania, and Yugoslavia are the most important producers of iron and steel products, and copper and lead are produced by Yugoslavia. Copper is the only metal exported from this region.

The extent of industrialization in southeastern Europe may be gleaned from certain Government decrees enacted during 1936. The Yugoslav Government restricted imports of various products by requiring preliminary authorizations from the National Bank. By a decision of the Ministry of Finance the restriction was made effective for all imports from France and Germany as of April 21, 1936. It

was reported that the purpose of this measure was to promote trade with countries that are heavy purchasers of Yugoslav products and to force countries that limit their imports by quota restrictions to increase the quotas on Yugoslav products. In March 1936 a Rumanian prohibition was placed on the exportation of copper in the form of ingots, plates, bars, and scrap. In July 1936 imports of copper plates and sheets into Czechoslovakia were made subject to permit requirements, and in June 1936 imports of black, unworked iron and steel sheets were likewise made subject to permit requirements. Exports of mercury from Czechoslovakia were made subject to export permit requirements in December 1936.

Italy.—Almost simultaneously with the recommendation of the League of Nations imposing on member countries restrictions on trade with Italy, the latter, in October 1935, prohibited publication of statistics on Italian foreign trade. Although the various countries had canceled the decrees restricting trade with Italy by July 1936, the official prohibition on publication of foreign trade statistics was not removed by December 1936. As a consequence, a comparative review of Italian trade cannot be made. However, Italy depends on foreign sources for most essential mineral raw materials except bauxite, mercury, zinc, gypsum, marble, and sulphur, of which it has exportable surpluses. Some antimony, copper, iron ore, lead, manganese, asbestos, barite, coal, fluorspar, graphite, magnesite, petroleum, potash, pyrites, and soapstone are produced, but the domestic reserves are wholly inadequate to meet requirements.

To insure an adequate supply of mineral raw materials for domestic consuming industries, the Italian Government issued decrees in December 1935 providing for the creation of three organizations to be responsible for the regulation and development of domestic mining activities and importation of essential minerals other than petroleum. Italian Mineral & Metal Corporation, a semiofficial agency, was established to aid in financing exploratory and development work in connection with domestic mineral deposits and to conduct mining operations when necessary. The Italian Coal Corporation, also a semigovernmental organization, was created to develop domestic coal deposits and to assist financially the principal coal producers of Istria and Sardinia, thus enabling them to increase production. The Mineral Products Board was created to regulate imports, domestic production, and distribution and to finance imports of minerals except petroleum and coal when necessary to maintain adequate supplies for national needs. This agency likewise exercises administrative functions for the afore-mentioned organizations. The fourth government agency, the Petroleum Board, was organized in October 1935 to supervise the activities of the Italian Petroleum Corporation and the Italian Corporation for Albanian Petroleum, which have served since 1926 as regulatory bodies for marketing petroleum products in Italy and for exploratory work.

These government organizations cooperate closely with the Fascist National Federation of Extractive Industries for mining companies and the Fascist National Federation of Mechanical and Metallurgical Industries for metallurgical and fabricating companies, both of which form a part of the National Confederation for Industry. Most Italian mining and metallurgical companies are now members of one or the other organization. Throughout 1936 these official and private agencies were actively concerned with the problem of increasing

domestic output of essential mineral raw materials and reducing imports of such products to a minimum. In Italy, as in Germany, the cost factor is considered as of secondary importance compared with attainment of the primary objective of national self-sufficiency.

Spain.—Although official Spanish production and foreign-trade statistics for 1936 are not available, shipments of those minerals of which the country produces an exportable surplus were maintained at a level approximating that for 1935. This fact is reflected by the tonnage of Spanish iron ore, mercury, pyrites, and pig lead received by principal consuming countries. France, Germany, the United Kingdom, and the United States account for more than 75 percent of the iron ore, 60 percent of the mercury, 55 percent of the pyrites, and 60 percent of the pig lead exported from Spain annually. Although Italy frequently has surpassed Spain in annual production of mercury, Spain has been the principal world producer since 1934. Of the total Spanish output in 1934, amounting to 31,799 flasks, the United Kingdom purchased 36 percent, the United States 20 percent, and France 8 percent. In 1935 and 1936 Germany became an important purchaser of Spanish mercury. Exports of mercury from Spain to France, Germany, the United Kingdom, and the United States in 1935 were approximately 41 percent greater than production during the year, which amounted to 35,560 flasks; the excess shipments were withdrawn from stocks. Exports to these countries in 1936 were about 23 percent below the 1935 level.

More than 50 percent of the crude pyrites produced in Spain is exported to France, Germany, the United Kingdom, and the United States. Exports to these four countries in 1934, which amounted to 1,050,790 metric tons, represent 51 percent of the total Spanish production during the year. Exports to these countries in 1935 totaled 1,456,858 metric tons and in 1936 decreased slightly to about 1,200,000 metric tons.

In 1936 exports of pig lead from Spain to France, the principal purchaser of Spanish lead, exceeded the tonnage shipped in 1934 and 1935, totaling 20,514 metric tons for the first 10 months of the year. Germany, the second largest importer of Spanish lead, purchased about 2,000 metric tons in 1936, or approximately the same quantity as in 1935. Italy is also an important buyer of Spanish pig lead, but as neither Spanish nor Italian foreign-trade statistics are available for 1936 no estimate of the tonnage involved can be made. Normally these three countries purchase approximately 60 percent of the total exports of lead from Spain.

Official import statistics indicate that Germany has become an outstanding buyer of Spanish iron ore, receiving 1,067,733 metric tons in 1936 compared with 1,320,596 tons in 1935 and 61,968 tons in 1934. French imports of iron ore from Spain during the first 10 months of 1936 were 43,462 tons compared with 35,259 tons in 1935. Although detailed figures covering imports into the United Kingdom are not available, there is evidence that the tonnage of Spanish ore shipped to the United Kingdom in 1936 was approximately the same as in 1935.

SOUTH AMERICA

Although national policies of many European countries are outstanding examples of evident determination to attain national self-sufficiency with regard to mineral raw materials, the tendency to

regulate or control international trade, as well as domestic industry, likewise has advanced in South American and Far Eastern countries. For example, in June 1936 a Bolivian decree empowered the exchange control board, in conjunction with the Central Bank of Bolivia, to exercise strict control over foreign trade by establishing import and export quotas and adopting measures tending to prohibit or restrict importation of products that are or may be produced in the country. Certain imports that are considered dispensable may be restricted temporarily or permanently at the discretion of the Board.

Under a Colombian decree, effective August 1, 1936, import licenses, previously obtained from the office of exchange and export control, are required for the importation of all merchandise into Colombia.

JAPAN

Japan and its possessions are little better off than Italy in domestic supplies of minerals. The known copper reserves are greater than in any other Far Eastern country, but they are inadequate to meet Japan's industrial requirements. From 1933 to 1935, 38 percent of Japan's apparent consumption of virgin refined copper was imported. Coal is probably the only primary industrial mineral of which Japan has sufficient reserves. During the period 1933-35, 92 percent of Japan's apparent consumption of crude petroleum and 80 percent of its pig-tin requirements was imported; moreover, 63 percent of its manganese ore was imported, although in the last few years that country has produced 2 to 3 percent of the world output of this mineral, so essential to its steel industry. Its reserves of iron ore are wholly inadequate to meet industrial demands. From 1933 to 1935, inclusive, 79 percent of its apparent consumption of iron ore was imported from countries other than Japanese possessions. In Japan, as in Italy, there are reserves of a few mineral raw materials, but output has been insufficient to meet domestic requirements. Japan's production of chrome ore in the past few years has been about 5 percent, its production of tungsten ore between 2 and 3 percent, and its production of zinc between 1 and 2 percent of the world output. In addition to these minerals it produces relatively small tonnages of antimony, mercury, platinum, asbestos, barite, china clay, fluorspar, graphite, mica, phosphate rock, pyrites, and sulphur, but the annual output is considerably less than current requirements.

Japan has promulgated a series of laws that regulate the domestic mining industry to a considerable extent, but to a greater degree these enactments enable manufacturers and consumers of imported raw materials to export finished, manufactured products to world markets under the most favorable competitive conditions. In 1931 the Japanese Government enacted a law which has two objectives for the control of principal or key industries of the country: (1) The strengthening and support of control measures, by which the Government is empowered to require nonmembers of a particular industrial union to abide by control agreements of such a union, provided the action is recommended by more than two-thirds of the total members of the union in question; and (2) the supervision of industrial control measures adopted by associations of industries, through which the Government is enabled to alter or abolish entirely industrial agreements considered adverse to the public interest or injurious to the best interests of the industry concerned or related industries.

The Export Indemnity Law of 1930 and a law for control of foreign trade enacted in 1934 were adopted to facilitate export financing to undeveloped markets, to protect Japanese export trade, and to equalize trade balances.

SERVICE OF BUREAU OF MINES

For a number of years the Bureau of Mines has collected, compiled, and published mineral-production statistics of foreign countries. For a detailed account of this phase of Bureau activity see *Minerals Yearbook*, 1935, page 21. Those who may wish to carry forward compilations heretofore prepared by the Bureau are referred to the principal tables on world production presented in the following chapters in this volume.

Aluminum	Fluorspar	Petroleum
Antimony	Graphite	Phosphate rock
Arsenic	Gypsum	Platinum
Asbestos	Iron ore	Potash
Barite	Pig iron	Pyrites
Bauxite	Lead	Salt
Briquets	Magnesite	Sulphur
Cadmium	Manganese	Talc and soapstone
Chromite	Mercury	Tin
Coal	Mica	Titanium
Coke	Molybdenum	Tungsten
Copper	Nickel	Vanadium
Feldspar	Oil shale	Zinc

Principal sources.—Data used in this chapter have been obtained from official production and foreign-trade statistical publications of Belgium, France, Germany, Italy, Japan, U. S. S. R. (Russia), United Kingdom, and United States; monthly German Metal and Mineral Notes, American consulate general, Frankfort-on-Main, Germany; Weekly Reports of the German Institute of Business Research, Berlin, Germany; Foreign Tariffs and Trade Regulations, Bureau of Foreign and Domestic Commerce, Washington, D. C.; and press releases, The Department of State, Washington, D. C.

DOMESTIC REFINERY PRODUCTION

The figures in the following table were obtained through cooperation between the United States Bureau of the Mint and the Bureau of Mines and were agreed upon after conference and adjustment between the two Bureaus.

The totals are based on bullion deposits in the United States mints and assay offices and on returns to the Bureau of the Mint from the smelting and refining companies. The distribution is adjusted by means of information collected by the Bureau of Mines directly from the producing mines and tabulated for the mine reports discussed later. The data for the total production and in part for the distribution are obtained from records of (1) the unrefined domestic gold and silver deposited in the United States mints and assay offices, (2) the domestic gold and silver in fine bars reported by private refineries, and (3) the unrefined domestic gold and silver contained in ore and matte exported for reduction. The last item is very small.

¹ Some of the data for 1936 are preliminary, as indicated; detailed statistics with final revisions will be released later

Approximate distribution of the production of gold and silver in the United States 1935-36, by producing States and Territories

¹ Gold valued at \$35 per ounce.

² Silver valued per ounce, as follows: 1935, at \$0.71875 (purchase rate for United States product); 1936, at 77 cents (approximate average purchase rate for United States product).

³ Preliminary estimate.

In 1935, as in 1934 and 1933, more old gold was returned from industrial to monetary use than was issued to the arts and industries, a condition that has continued since 1932; returns for 1935 totaled

1,668,305 ounces and issues 740,843 ounces, a net return of 927,462 ounces. The total quantity of silver (new and old) used in the arts and industries was 41,192,023 ounces, 1,513,420 ounces more than in 1934. In addition to the gold and silver derived from foreign and domestic ore and bullion 1,668,305 ounces of gold and 35,903,107 ounces of silver were recovered from old or obsolete jewelry, silverware, dental waste, old film, and other material.

*Gold and silver produced in the United States, 1792-1936*¹

[The estimate for 1792-1872 is by R. W. Raymond, commissioner, and for the period since 1872 by the Director of the Mint]

¹ Gold valued per fine ounce as follows: Prior to 1933, \$20.67+; 1933, \$25.56; 1934-36, \$35.

² Subject to revision.

The average commercial value per fine ounce of silver for the total recorded domestic production is \$0.777.

REGULATIONS AND EXECUTIVE ORDERS RELATING TO GOLD AND SILVER OF DOMESTIC ORIGIN

A complete account of the regulations pertaining to gold and silver is given in the chapter on Gold and Silver in Minerals Yearbook, 1934, pp. 25-46, issued by the United States Bureau of Mines.

Monetary relationships.—United States coinage laws show the development of the establishment of the value of \$20.671834625323 per troy ounce of gold. The following table of laws gives the value of gold per troy ounce under different congressional acts, using the eagle (\$10 gold coin), although no longer coined, as a basis.

Value of gold per troy ounce under different congressional acts

Date of law	Standard weight (grains)	Fineness (1000ths)	Fine gold content (grains)	Value per fine ounce troy (480 grains)	Value per grain
Apr. 2, 1792.....	270	916.6666+	247.5	\$19.393939	\$0.04040404
June 28, 1834.....	258	899.2248+	232.0	20.689656	.04310345
Jan. 18, 1837.....	258	900.0000	232.2	20.671835	.04306632
Mar. 4, 1900.....	258	900.0000	232.2	20.671835	.04306632
Jan. 31, 1934.....	152	900.0000	137.1	35.000000	.07291660

PRICES OF GOLD AND SILVER

Gold.—The United States Treasury buying price for gold remained at \$35 per ounce throughout 1935 and 1936. The following table shows the monthly extremes of gold prices in London from January 1931 to December 1936, inclusive.

Gold prices in London, 1931-36

¹ British gold standard suspended Sept. 21, 1931.

Silver.—On January 1, 1935, the United States Treasury buying price for newly mined silver stood at \$0.64646464+ (one-half of the coinage value of \$1.29292929+). On April 10, 1935, the Treasury raised the price to \$0.7111+ and on April 24, to \$0.7757+; this price was maintained throughout the remainder of 1935 and all of 1936 and was in effect when this report was written (June 12, 1937). The extreme monthly prices of silver in New York for 1935 and 1936, by months, have been as follows:

Silver prices in New York, 1935-36, in cents per ounce

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

DOMESTIC SUPPLY

The domestic supply of new gold comes chiefly from dry and siliceous ore and from placer gravel worked largely by dredges. These two sources yielded 90.2 percent of the domestic gold in 1915, 79.86 percent in 1930, 86.5 percent in 1931, 92.9 percent in 1932, 92.94 percent in 1933, 92.68 percent in 1934, and 90.55 percent in 1935. The proportionate output of gold from copper ore was 7.2 percent in 1915, 16.4 percent in 1926, 22.2 percent in 1929, 9.65 percent in 1931, 5.25 percent in 1934, and 7.01 percent in 1935.

In 1915 dry and siliceous ore yielded 36 percent of the total silver; copper ore, 26 percent; lead ore, 27 percent; and lead-zinc ore, only 9 percent. In 1935 dry and siliceous ore yielded 40.02 percent; copper ore, 26.15 percent; lead ore, 6.89 percent; and lead-zinc ore, 26.60 percent.

WORLD PRODUCTION

GOLD

According to the Bureau of the Mint, the estimated quantity of gold produced in the world from 1860 to 1935, inclusive, is 975,246,364 fine ounces. For 1935 alone it is estimated at 30,001,209 ounces, an increase of 2,628,835 ounces over 1934.

In a Bureau of Mines publication,² the world output of gold from 1493 to 1927, inclusive, is estimated as approximately 1,003,560,000 ounces, of which 51.5 percent was produced from 1901 to 1927. Adding to this the production (188,153,881 ounces) from 1928 to 1935, inclusive, makes an estimated total from 1493 to 1935 of approximately 1,191,714,000 ounces.

The following table shows the output of gold by countries from 1931 to 1935, as estimated by the Bureau of the Mint.

SILVER

The Bureau of the Mint estimates the world production of silver from 1860 to 1935, inclusive, as 10,755,949,903 fine ounces. The output was 25,550,429 ounces more in 1935 than in 1934.

The following table shows the output of silver by countries, 1931 to 1935, inclusive, as estimated by the Bureau of the Mint:

MINE REPORT

METHOD OF COLLECTING STATISTICS

The first table in this report presents the official refinery figures of the production of gold and silver in the United States in 1935 and 1936, as agreed upon by the Bureau of the Mint and the Bureau of Mines. With the comparatively unimportant exceptions of domestic gold and silver contained in ore and matte exported for reduction during the

year, these figures record the production of gold and silver bullion from domestic ore in marketable form as metals, either refined or unrefined.

To trace the gold and silver produced back to its source by States, counties, and mining districts, the Bureau of Mines systematically investigates the "mine production" of ores containing gold and silver and the output of the placer mines, the total being classified by methods of production and by kinds of ore, as well as by mining districts. The resulting figures form the basis of the mine reports.

Of the two plans for ascertaining the production of gold and silver, one is a measure of the metallurgic industry and the other of the mining industry; one reports the metal actually recovered in marketable form and the other the mine output and its recoverable content. The two methods will not produce identical results, but the figures for a period of years sufficiently long to compensate for overlap or lag should agree within allowable limits of error.

Gold and silver produced in the United States, 1905-35, according to mint and mine returns

Year	Mint		Mine	
	Gold ¹	Silver	Gold ¹	Silver
		<i>Fine ounces</i>		<i>Fine ounces</i>
1905-31.....	\$1,929,861,500	1,636,641,604	\$1,917,814,501	1,626,080,695
1932.....	50,626,000	23,980,773	53,218,073	22,899,865
1933.....	65,337,600	23,002,629	67,191,498	23,317,159
1934.....	108,191,400	32,725,353	109,014,594	32,995,017
1935.....	126,324,900	45,924,454	129,109,115	48,840,669
Total, 1905-35.....	2,280,341,400	1,762,274,813	2,276,347,781	1,754,133,405
Fine ounces of gold.....	105,062,800		104,785,467	

¹ Gold valued per fine ounce as follows: Prior to 1933, at \$20.67+; 1933, at \$25.56; 1934, mint at \$35 and mine at \$34.95; 1935, at \$35.

According to mint reports, these figures show a total excess of gold for the 31 years of 277,333 ounces (a difference of 0.26 percent) and a total excess of silver of 8,141,408 ounces (a difference of 0.46 percent).

UNITS OF MEASUREMENT

In the measurement of ores and concentrates the short ton of 2,000 pounds is used.

Throughout 1932 and earlier years the price of gold was fixed by law at \$20.67+ per fine ounce, and in 1933 the legal coinage value was continued at \$20.67+. The average weighted price per fine ounce, as computed by the Bureau of Mines, was \$25.56 for the year 1933, \$34.95 for 1934, and \$35 for 1935 and 1936.

The annual average prices for domestic silver from 1931 to 1936 are as follows: 1931, \$0.290; 1932, \$0.282; 1933, \$0.350; 1934, \$0.64646464+; 1935, \$0.71875; 1936, \$0.7745.

MINES PRODUCING

LEADING GOLD PRODUCERS

The output of the 25 largest gold producers in the United States (Philippine Islands and Puerto Rico excluded) in 1936, none of which

produced less than 17,500 ounces, was 2,022,500 fine ounces (53.7 percent of the total); in 1935 none of the group produced less than 13,800 ounces, and the total output was 1,795,000 ounces (55.5 percent of the total); and in 1934, none produced less than 15,600 ounces, and the total group output was 1,660,900 ounces (60 percent of the total). The successive decreases in 1935 and 1936 from 1934 in the proportion of the total gold produced by the 25 largest operators indicate, as anticipated, that lower-grade gold ores were treated at the larger lode mines and that new mines and smaller mines were responsible for a large part of the increase in output of gold. Operators of gold dredges increased their output 89,558 ounces in 1936 over 1935 compared with only 2,595 ounces in 1935 over 1934. The average recovery of gold per ton of dry and siliceous ores decreased from 0.156 ounce in 1934 to 0.154 ounce in 1935.

The Homestake lode mine in South Dakota was the largest producer of gold in both 1935 and 1936, as for many years past. In 1935 the Golden Cycle Corporation (custom mill) in Colorado was the second largest producer, but in 1936 second place was taken by the Phelps Dodge Corporation (combined output of company mines in three copper-producing districts). The Fairbanks Exploration Co. in Alaska (gold derived from dredging gravel) was the third largest producer in both years.

Larger producers of gold in the United States, 1935-36, in order of output¹

¹ Custom mill. Includes mainly ore from Cresson, Portland, Ajax, and other mines in Cripple Creek district, Colorado, but also from other districts in Colorado.

In 1936 the 25 largest producers of gold were distributed as follows: 12 in California, 3 each in Alaska, Colorado, and Utah, 2 in Nevada, and 1 each in Arizona and South Dakota; of these companies 15 produced gold from dry and siliceous ores, 6 from gravel by floating dredges, 3 from copper ore, and 1 from combined lead ore, lead-zinc ore, and siliceous ore. In 1935 there were 11 in California, 4 in Alaska, 3 in Colorado, 2 in Utah, and 1 each in Arizona, Idaho, Nevada, New Mexico, and South Dakota; of these companies 14 produced gold from dry and siliceous ores, 6 from gravel by floating dredges, 3 from copper ore, 1 from lead-zinc ore, and 1 from combined lead ore, lead-zinc ore, and siliceous ore.

The Benguet Consolidated Mining Co. (including the Balatoc mine, controlled by Benguet stockholders) in the Philippine Islands ranked between the Homestake mine and the Golden Cycle Corporation as a gold producer in 1935; its output increased in 1935 from 1934 and has shown a large increase again in 1936.

LEADING SILVER PRODUCERS

The output of silver from the 25 leading producing companies in 1936, none of which produced less than 310,000 ounces, was 42,011,500 ounces, or 69 percent of the mine total (Philippine Islands and Puerto Rico excluded). Of these companies 7 were operating in Utah, 4 in Idaho, 3 each in Arizona, Montana, and Nevada, 2 in Colorado, and 1 each in California, New Mexico, and Texas; 8 of the companies recovered silver from dry and siliceous ore, 7 from zinc-lead ore, 4 from copper ore, 2 from lead ore, 1 from copper-lead-zinc ore, 2 from combined lead, lead-zinc, and siliceous ores, and 1 from combined copper, zinc-lead, and silver ores.

24	Eureka Standard Mining Co.	Utah.....	Tintic.....	Dry and siliceous ore.
25	G. A. Franz.	Colorado.....	Uncompahgre.....	Do.

In 1935 the output from the 25 leading silver-producing companies was nearly 36,865,000 ounces, or 76 percent of the mine total (Philippine Islands and Puerto Rico excluded). Ten of these companies (4 in Idaho, 3 in Utah, and 1 each in Arizona, Colorado, and Montana) produced more than 1,000,000 ounces each, and none yielded less than 218,000 ounces; 6 were in Utah, 5 in Arizona, 4 in Idaho, 3 each in Montana and Nevada, 2 in New Mexico, and 1 each in Colorado and Texas. Only four of these large producers derived all their silver from dry and siliceous ores; the great bulk of the silver came from base ores, mainly lead-zinc and copper ores.

NUMBER OF MINES

The following table indicates the number of mines that produced gold and silver in 1935. The placers are those in which the gold and the silver in natural alloy with the gold and, in a few placers, with platinum are recovered from gravel and sand, whether by hand washing, sluicing, hydraulicking, drifting (in frozen ground or ancient buried river channels), or dredging. The lode mines are those yielding gold and silver (from ore as distinguished from gravel) mainly from underground workings, including those that yield ore valuable chiefly for copper, lead, or zinc but that contribute precious metals as byproducts. In addition to producing mines enumerated here many properties were being prospected and developed, and many other mining claims were being held by assessment work only.

The enumeration of placer mines is less satisfactory than that of lode mines, because some are operated only temporarily and are individually small and because much of the production is made by transitory miners not regularly working placer ground. So far as possible the unit, as for lode mines, is not the operator but the mining claim or group of claims.

Number of mines in the United States producing gold and silver in 1935, by States ¹

¹ Gold valued per fine ounce as follows: Prior to 1933, \$20.67+; 1933, \$25.56; 1934, \$34.95; 1935, \$35.

ORE PRODUCTION, CLASSIFICATION, METAL YIELD, AND METHODS OF RECOVERY

The best index of lode mining is the quantity and metallic content of ore mined rather than the number of mines or operators. The following tables give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that produced gold and silver in the United States (excluding the Philippine Islands and Puerto Rico) in 1935. The individual State chapters from which these tables were compiled contain additional tables and text on the subject and may be found elsewhere in this volume.

The classification originally adopted in 1905 on the basis of smelter terminology and recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in recovery of metals and the lowering of grade of complex ores treated, accomplished by improved mill concentration processes. A "dry" ore is one that carries so little lead or copper that by itself in quantity it would not satisfy the requirements for the smelter charge in lead smelting or copper smelting, respectively. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper (or less than this percentage if no other metal is present), or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay [should be 7.5 to 8.5 percent—C. W. H.] or more of lead, irrespective of precious-metal content; an ore that carries any grade of lead exclusively is called a lead ore. Zinc smelting ores (chiefly oxides) range from 16 to 45 percent zinc; zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated. In the tables that follow, figures for dry and siliceous ores have not been separated into gold, gold-silver, and silver ores. Siliceous

(silica ³ in excess of iron) gold, gold-silver, and silver ores containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed ores are called "dry" ores regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry and siliceous ores" thus, by elimination, include both dry siliceous and irony, but chiefly siliceous, ores valuable for their gold and silver content, regardless of method of treatment, and dry fluxing ores carrying considerable quantities of iron and manganese oxides, or iron sulphide, and very small quantities of gold and silver. The smelter classification applies to concentrates.

The lead, zinc, and lead-zinc ores in most districts in the Eastern and Central States carry no appreciable quantity of gold or silver; such ores are excluded from this report.

³ Except where mineralization approaches a matte, ores in their natural state generally contain more silica than iron and usually are highly siliceous.

Ore produced in the United States and average recovery in fine ounces of gold and silver per ton, 1931-35¹

¹ Illinois, Missouri, Philippine Islands, and Puerto Rico excluded; quantity of crude ore containing gold and silver unknown.

² Current slag furnished.

³ Includes pyritiferous magnetite ore from Pennsylvania yielding 8,709 tons of copper concentrates.

⁴ Zinc ore yielded no gold or silver.

⁵ Figures represent New York and Tennessee lead-zinc ores. Lead-zinc ore from Virginia yielded no gold or silver.

¹ Philippine Islands and Puerto Rico excluded.

PLACERS

Dredging.—Placer gold is obtained chiefly from gravel handled by connected-bucket floating dredges, which recovered 66 percent of the total output from placers in the United States (Philippine Islands and Puerto Rico excluded) in 1936 and 67.11 percent in 1935. The quantity of gold recovered by dredges from the inception of the industry as a commercial factor in 1896 to the end of 1935 is recorded as 13,855,909 ounces, originating by States as follows: California, 9,076,624 ounces; Alaska, 3,151,495 ounces; Montana, 494,909 ounces; Colorado, 415,922 ounces; Idaho, 376,767 ounces; Oregon, 305,791 ounces; and other States, 34,401 ounces. The output in 1936 was 605,307 ounces from 103 dredges, of which California produced 285,691 ounces from 45 dredges; Alaska, 255,803 ounces from 38 dredges; Idaho, 26,098 ounces from 12 dredges; Montana, 19,120 ounces from 2 dredges; Oregon, 17,067 ounces from 5 dredges; and Colorado, 1,528 ounces from 1 dredge.

¹ Arizona, Colorado, Idaho, Montana, and Oregon.

Other placer-mining methods.—From 1932 through 1936 dragline and power-shovel excavators operated in connection with dry-land and floating amalgamating and sluicing plants have been widely used in placer mining. In 1936, 16 percent of the total output of placer gold was recovered at these plants, and 18 percent was produced by old established mining methods such as hydraulicking, drift mining, sluicing, and rocking.

Additional information on placer-mining methods may be found in the State reviews in Minerals Yearbook and Mineral Resources.

PRODUCTION IN PHILIPPINE ISLANDS

The value ⁴ of the gold produced in the Philippine Islands from 1907 to 1935, inclusive, is recorded as \$77,128,126. The value ⁴ of the output during the last 10 years was as follows:

1927-----	\$1, 686, 231	1932-----	\$5, 050, 084
1928-----	1, 904, 062	1933-----	8, 308, 009
1929-----	3, 320, 300	1934-----	11, 893, 975
1930-----	3, 704, 800	1935-----	15, 813, 630
1931-----	3, 762, 433	1936-----	¹ 20, 987, 995

¹ Refinery receipts.

The output was considerably larger in 1936 than it was in 1935, as several new mills were in operation. Among the larger producing mines are: Benguet Consolidated, Balatoc, Itogen, Antamok, Demonstration, Baguio, Suyoc, Penique, Benguet Exploration, Ipo, United Paracle, I X L, Masbate Consolidated Atok, and Salacot. The milling capacity of many of the mines was increased in 1936 and some new mills were built.

The gold dredges operated in the Philippine Islands in 1935 were those of the Tambis Gold Dredging Co. and the Coco Grove, Inc. Their recovery was comparatively small in 1935, but they were being operated on a much larger scale in 1936, so that their output of gold will show a large increase.

⁴ Gold valued per fine ounce as follows: Prior to 1933, \$20.67+; 1934, \$34.95; 1935 and 1936, \$35.

The salient features of the copper industry in 1936 include the increase in apparent world consumption, the influence of the London market upon price in the United States, the substantial reduction in domestic and world stocks, and the apparent shift in the burden of financing stocks.

Except in 1929, world requirements of copper in 1936 were the highest on record, approximating 112 percent of the annual average for 1925-29. The domination of foreign price over that in the United States in the last quarter of 1936 marked one of the major changes in the economics of the copper industry. From September on, despite a tariff of 4 cents a pound on metal imported into the United States, the price of copper was higher in the international market than in New York. There was considerable lag between the rapid price advances in the international market and price changes in the domestic trade. Another important factor was the notable decrease in world stocks of refined copper, which were 353,000 tons on December 31 (132,000 tons less than at the end of 1935) and probably not much more than half the record inventories on hand at the end of 1932. Basic statistics for stocks of copper held by manufacturers or in the hands of speculators are not available. The abnormally large sales of copper for advance future delivery at extended periods indicate that the burden of financing stocks has shifted in part from the producer to the consumer and speculator.

For many years the United States consumed more copper than continental Europe, but in 1931 this condition was reversed. The peak of consumption in the United States was reached in 1929, whereas Europe attained it in 1936.

Apparent consumption of copper in the United States in 1936 was 656,179 tons, 49 percent larger than in 1935 and 84 percent of the

annual average for 1925-29. Largely because of the incomplete nature of data on stocks, the figures of apparent consumption for any year do not represent the actual tonnage of copper that may have entered into consumptive channels. (See table, p. 155.) They are useful, however, in indicating trends.

Salient statistics of the copper industry in the United States, 1925-29 (average) and 1933-36, in short tons

¹ Subject to revision.

² Includes old tailings.

³ Figures not yet available.

⁴ Data for 1934-36 include copper imported for immediate consumption plus material entering the country under bond as do figures for earlier years.

⁵ Total exports of copper, exclusive of ore, concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper" for which figures of quantity are not recorded.

⁶ Approximate.

Efforts to control price.—The price of copper advanced abruptly in the last quarter of the year after holding within narrow limits during months of record-breaking sales. In April, July, and October, successive new high-record sales for a single month were made in the domestic market. Notwithstanding these record sales, the average monthly price for electrolytic copper, f. o. b. refinery, was only 9.563 cents a pound in October compared with 9.025 cents in January. In consequence of the continued heavy purchases of copper in November and December, following the already heavy drain on supplies, the price moved up to 11.775 cents a pound on the last day of the year. This vigorous upswing continued at an accelerated rate until the price reached 16.775 cents on March 31, 1937. Producers in the United States and abroad increased their rates of production greatly in the latter part of 1936 in an apparent attempt to maintain a conservative price policy, in order to encourage a continuation of the increasing rate of consumption and to discourage substitution and the opening up of marginal mines. The record sales and sharply rising prices

were brought about largely by greater industrial demand from abroad, increased demands for armaments because of disturbed political conditions in some of the large industrial countries of the world, threatened devaluation of currencies, and, chiefly as a result of the foregoing, increased speculation on the London Metal Exchange. The division of domestic bookings for December 1936, published in the American Metal Market, showing a large quantity for far-forward delivery, is in part an indication of the speculative nature of sales in that month:

	<i>Delivery</i>	<i>Short tons</i>
December.....	-----	2, 951
January.....	-----	855
February.....	-----	1, 080
March.....	-----	71, 162
April and beyond.....	-----	41, 667
		<hr/> 117, 715

The efforts of producers outside of the United States in 1935 and the first part of 1936 to bring output into line with consumptive requirements lowered inventories and probably contributed to the tenseness of conditions late in 1936 and early in 1937. (In April 1936 the restriction agreement was extended to July 1, 1938, as announced in *Minerals Yearbook*, 1936, p. 109). At the end of 1936, foreign producers who were parties to the production-control agreement were operating at 105 percent of their quota basis compared with 70 percent prior to August 1. Early in January 1937 all restrictions on production were removed. That this action failed to dampen the enthusiasm of consumers and speculators for the metal is attested by continued large sales resulting in the increase in price, already mentioned, to 16.775 cents a pound in March 1937.

Historical résumé.—A brief résumé of the history of the copper industry during the last 16 years is given below to clarify, in part, some of the conditions mentioned that affected the domestic copper industry at the close of the year and to indicate the trends that became dominant factors in the last quarter of 1936.

Due to a large excess of production over consumption, the majority of the copper mines in the United States closed down in 1921. At the end of the first quarter of that year the refined stocks of copper in hands of producers in the United States and Chile were 366,099 short tons. To relieve the situation, a Copper Exporters Association was formed, and this corporation arranged for the financing of 200,000 tons of copper, to be marketed only in the export trade. Partly as a result of these measures and partly because of the rapid recovery of industry from the depression of 1921, stocks were reduced to 98,845 tons by the end of the second quarter of 1923. In the latter part of 1924, however, it became evident that production once more exceeded consumption and that stocks again were accumulating. On October 12, 1926, the Copper Exporters, Inc., an association of American copper producers, and certain foreign producers and sellers of copper, was organized under the provisions of the Webb-Pomerene Act. The association represented, broadly, the control of approximately 90 percent of the world copper production. The purpose of the organization was to endeavor to "eliminate in foreign countries the harmful speculation that causes wide fluctuations in price, unwarranted by industrial factors in European markets, and tends to destroy

confidence in the integrity of such price and the stability of business."

On December 31, 1926, the stocks of refined copper in North and South America totaled 85,501 short tons. The average quoted price of electrolytic copper f. o. b. refinery for the year was 13.795 cents a pound. At the close of December 1927 stocks were 95,298 tons, and the average price for the year was 12.920 cents a pound. At the close of December 1929 stocks of refined copper were 171,320 tons, and the average price for the year was 18.107 cents a pound. On December 31, 1929, stocks of blister and refined copper in North and South American amounted to 439,726 tons. During the month of January 1929 the high price of electrolytic copper was 16.775 cents a pound. In March it reached a maximum of 23.775 cents and in April receded to 17.775 cents, where it remained until the following April. The effect of this price was to accelerate the development of copper mines throughout the world, particularly in South Africa and Canada. In 1930 the British Empire became self-sufficient as to its copper requirements and for the first time since 1880 had an exportable surplus. Increased production from the newly developed districts, combined with the falling off in demand due to world-wide depression as well as the accumulations of stocks and the steady supply of secondary copper, reduced the world price to a low of 5 cents in December 1932. Drastic curtailment was inaugurated, but the latent capacity for production, from a world standpoint, was almost one-third greater than the peak of world consumption. Between 1929 and 1936 the relation of the leading copper-producing countries to world production changed appreciably. The following table shows changes in proportions of the world total supplied by the leading countries. The effect of the curtailment agreement on the alignment in 1936 is apparent.

	1929 (percent)	1935 (percent)	1936 (percent)
United States.....	48	23	31
Chile.....	16	17	14
Rhodesia.....	0.3	10	8
Canada.....	4	11	10
Belgian Congo.....	7	7	?

During the period 1922-29, when the United States supplied more than 70 percent of the world demand from domestic mines and those controlled in foreign countries, the domestic copper producers could inaugurate policies that were world-wide in their effect, and through the Copper Exporters, Inc., controlled both exports and world price. One of the first acts of this association was to abolish the speculative control of price that had been exercised for many years by the London Metal Exchange, and for the first time in the history of domestic production world price was established in New York; this condition was made possible largely by the circumstances outlined above, indicating that the British Empire could not satisfy its copper requirements and had to purchase the major part of its needs from the United States. As the mines of South Africa and Canada came into production and, with the Belgian holdings, proved capable of supplying the larger part of the needs of the industrial nations outside of the United States, the London Metal Exchange was again able to function, and in the latter part of 1936 it became evident that the price of copper was being established once more in London and not in New York.

During the latter half of 1936 the domestic producers on five different occasions felt that it was necessary to meet the advance in foreign price. At the same time, owing to the high price for copper, many marginal mines in the United States that had been closed by the depression were reopened. The low-cost copper producers inaugurated the policy of full production to build up producers' stocks and attempt to overcome the uneconomic distribution of available copper. The present trends differ so slightly from what has gone before it seems probable that in the near future the history of the industry will not deviate materially from that of the past.

United States and world reserves.—According to an estimate by Ira B. Joralemon, W. W. Lynch, and C. K. Leith in connection with Arizona tax legislation in 1935 (quoted in *Minerals Yearbook*, 1936), a total of 17,602,000 tons of metallic copper was minable at equipped properties in the United States at a cost below 10 cents a pound, and an additional 4,210,000 tons at above 10 cents, with some 4,310,000 tons more minable in unequipped properties, where the cost of mining was uncertain.

Barbour's¹ estimate of copper-metal reserves for the United States was 30,000,000 to 35,000,000 tons of metal, of which 20,000,000 were officially reported. His estimate for the world was:

Country	Short tons	Country	Short tons
United States.....	20, 992, 700	Belgian Congo.....	6, 511, 000
Canada.....	5, 620, 200	Russia.....	10, 851, 000
Chile.....	35, 498, 500	All other.....	2, 961, 400
Rhodesia.....	22, 395, 400		
			104, 830, 200

Effects of price on consumption.—The major use for copper is in the electrical trades, and no substitute has been found that meets to the same efficient degree the chemical and physical requirements demanded by this industry. During the period of high prices, however, many of the transmission lines built throughout the United States were made of aluminum. At price, aluminum pig and that of copper are commercially interchangeable. Notwithstanding the drop in the price of copper, aluminum has held its own in this phase of the industry.

In the building trades, for other than electrical household equipment, the use of copper by the architect or building contractor is a matter of cost. According to the Copper and Brass Research Association, the indications were that although less than half as much money was expended in building in 1936 as in 1929, the consumption of brass pipe and copper tubing in 1936 was estimated to have exceeded the consumption in any previous year by 15,000,000 pounds. The same authority stated that there was a substantial increase in the use of copper for roofs and flashings, gutters and downspouts in 1936, that 10,000,000 pounds more copper were consumed by manufacturers of mechanical refrigeration than in any other 12-month period, that 20,000,000 feet of copper tubing were used by manufacturers of oil burners, more than in any previous year, and that the consumption of copper by the radio industry was of record proportions in 1936.

High prices for copper curtail its use in such materials as spandrels, down-takes and roofing, as well as in various forms of hardware when

¹ Barbour, Percy E., *World Copper-Ore Reserves*: Eng. and Min. Jour., vol. 135, no. 10, New York, October 1934, pp. 448-449.

copper, aluminum, rustless steel, lead, and zinc meet in a highly competitive market.

Wide fluctuations in price ultimately are reflected in the consumption of any metal, and copper is not an exception.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled on a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographical distribution of production; smelter figures are better for showing the actual recovery of metal and are fairly accurate for showing source of production; and refinery statistics give precise information regarding metal recovered but indicate in a general way only the source of crude materials treated. The chapter on Copper in *Mineral Resources, 1930*, contains a discussion of the differences among the three sets of figures.

Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1932-36, in pounds

Year	Mine	Smelter	Refinery

PRIMARY COPPER

Smelter production.—The recovery of copper by United States smelters from ores of domestic origin amounted to 1,222,819,396 pounds in 1936, an increase of 60 percent over the total for 1935, which, in turn, was 56 percent larger than that in 1934. The 1936 production was 31 percent of the world smelter total and marked a notable improvement over 1935, when domestic smelter production was only 23 percent. During the period 1925-29, however, the United States produced 51 percent of the world smelter-copper output.

The figures for smelter production in 1936 are based on confidential returns from all smelters handling copper-bearing materials produced in the United States. For Michigan, the sum of furnace-refined copper and copper cast into anodes for electrolytic refining is included. The figures for blister represent the fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production. Metallic and cement copper recovered by leaching also is included in smelter production.

The precise quantity, in pounds, of copper produced by smelters in the United States and its value are shown by years for 1845-1930 in the Copper chapter of *Mineral Resources of the United States, 1930*. The data are summarized for comparison with those for 1931-36, in the following table.

Copper produced in the United States from domestic ores, 1932-36

[Smelter output, in pounds fine]

State	1932	1933	1934	1935	1936

Mine production.—The figures for mine production are based on reports furnished to the Bureau of Mines by all domestic mines that produce copper. Details of the method of collecting the statistics and reasons for the discrepancy between mine-, smelter-, and refinery-production figures are given in the Copper chapter of Mineral Resources of the United States, 1930.

Mine production is more accurate than either refinery or smelter production for showing the distribution of domestic production by States and districts. It also indicates the ore production by calendar years more exactly because additional time is required for smelting and refining. Mine production in 1936 was 1,201,422,000 pounds, an increase of 58 percent over that in 1935 but still 32 percent below the average for 1925-29.

Production by States and districts.—The following tables show mine and smelter production by States for 1935 and 1936 and by districts for 1930–36. In 1936 Arizona, Utah, Montana, Nevada, and Michigan led in production, with 92 percent of the smelter total, the same percentage as in 1935.

The five States that produced most of the output in 1936 also produced by far the greater part of the output for 1845–1936, with some change in the order of magnitude. Arizona had the largest total for 1845–1936, followed in order by Montana, Michigan, Utah, and Nevada, their total output amounting to 89 percent of that for the entire United States. It is interesting that Arizona produced a slightly higher percentage of the total in 1936 than in 1845–1936, 33.87 percent compared with 32.82 percent, that Montana's share dropped from 22.49 to 17.62 percent, and Michigan's from 18.06 to 7.45, while Utah's jumped from 10.90 to 21.36 and Nevada's from 4.53 to 11.95.

The principal copper-producing districts in the United States for 1845–1936 were, in the order named, Butte, Mont.; Lake Superior, Mich.; Bingham, Utah; and Bisbee, Ariz.

Details of production, by districts and companies, in 1936 are available in other chapters of this volume dealing with production of gold, silver, copper, lead, and zinc in the various States.

¹ Districts producing 1,000 short tons or more in any year of the period, 1932-36.

² Data not yet available.

³ Bureau of Mines not at liberty to publish figures.

⁴ Subject to revision.

⁵ Includes a small quantity produced elsewhere in State.

⁶ Total for Alaska was 15 tons in 1933 and 57 tons in 1934.

⁷ Not listed in order of output.

Quantity and estimated recoverable content of copper-bearing ores.—The following tables list the quantity and the estimated recoverable copper content of the ore produced by United States mines in 1935; figures for 1936 are not yet available. Of the total copper produced from copper ores in the United States in 1935, 75 percent was obtained from ores concentrated before smelting, 1 percent from ores leached, and 24 percent from direct-smelting ore. In 1934 the figures were 73 percent from concentrated ore and 27 percent from direct-smelting ore.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that the estimated recoverable tenor is close to the actual recovery. Classification of some of the complex western ores is difficult and more or less arbitrary. Under copper ores are grouped not only those that contain 2.5 percent or more copper but also those that contain less than this percentage if they are valuable chiefly for copper. Under copper-lead and copper-lead-zinc ores are classed complex ores in which copper is a valuable constituent. Mines report considerable copper from ores mined primarily for other metals. These include siliceous gold and silver ores, lead and zinc ores, and pyritic sulphur ores.

The last table in the group, covering copper ores treated, indicates that producers respond to lower prices for metal by confining production to ores of higher grades. Copper prices began to fall sharply in 1930 and dropped from an annual quoted average of 18.11 cents a pound in 1929 to a low point of 5.56 cents in 1932. The average annual price increased steadily from 1932 until it reached 9.47 cents a pound in 1936. Conversely, the grade of ore improved with falling prices and dropped as prices rose. The average grade of ore treated for 1927-29 stood at 1.41 percent copper. The grade improved in each succeeding year through 1933, when the average reached 2.11 percent, the output of 1933 being under the influence of the record low price of December 1932. As prices improved and output increased, the grade fell to 1.92 percent in 1934 and 1.89 percent in 1935.

Figures for 1936 are not yet available, but the indications are that the grade of ore dropped further.

¹ Includes old tailings, etc.

² Includes old tailings, etc. Exclusive of small quantities from California which the Bureau of Mines is not at liberty to publish.

REFINERY PRODUCTION

The refinery output of copper in the United States in 1936 was made by 10 plants; 8 of these employed the electrolytic method, and 2 employed the furnace process on Lake Superior copper.

There are five large electrolytic refineries on the Atlantic seaboard, three lake refineries on the Great Lakes, and four refineries west of the Great Lakes—one at Great Falls, Mont.; one at Tacoma, Wash.; one at El Paso, Tex.; and one at Clifton, Ariz. Of the above plants,

the lake refinery of the Quincy Mining Co. and the plant of the Phelps Dodge Corporation that produces furnace-refined copper at Clifton, Ariz., have been idle since 1933.

In addition to the plants mentioned above, plants at Ajo and Inspiration, Ariz., are equipped to make electrolytically refined copper direct from the liquors obtained from leaching operations; this copper is shipped as cathodes to other refineries, where it is melted and cast into merchant shapes. The Inspiration plant was idle during 1933 and 1934, but operations were resumed during the latter part of 1935. The Ajo plant has been idle since 1931.

The above 14 plants constitute what is commonly referred to as "regular refineries." Of these plants, 10 employ the electrolytic process and 4 the furnace process. The electrolytic plants, excluding the Ajo unit which is no longer active, have a rated capacity of 1,612,000 tons of refined copper per annum. As they produced only 908,694 tons in 1936, only 56 percent of the electrolytic refining capacity was utilized. At the end of the year, however, they were producing at a considerably higher rate than that indicated for the year as a whole.

Refined copper is marketed in various grades, such as casting copper, lake copper, and electrolytic copper, and in various forms, such as wire bars, cathodes, and cakes. The differences in these various grades were explained on page 739 of the Copper chapter of Mineral Resources, 1930. The following tables show the production of refined copper at regular refining plants, classified according to source, grade, and form in which it was cast.

Primary and secondary copper produced by regular refining plants in the United States and imported, 1932-36, in pounds

	1932	1933	1934	1935	1936

¹ The separation of refined copper into metal of domestic and foreign origin is only approximate, as an accurate separation at this stage of manufacture is not possible.

² Some copper from Michigan was electrolytically refined at an eastern refinery and is included as electrolytic copper.

³ Data for 1934-36 include copper imported for immediate consumption plus material entering the country under bond as do figures for earlier years.

Copper cast in different forms in the United States in 1935-36

Form	1935		1936	
	Pounds	Percent	Pounds	Percent
Wire bars.....	642,000,000	43.53	983,000,000	51.44
Cathodes.....	874,000,000	25.36	329,000,000	17.22
Cakes.....	281,000,000	17.69	342,000,000	17.89
Ingots.....	71,000,000	4.81	112,000,000	5.86
Other forms.....	127,000,000	8.61	145,000,000	7.69
	1,475,000,000	100.00	1,911,000,000	100.00

Besides the regular refineries, numerous plants throughout the country operate on scrap exclusively, producing metallic copper and a great variety of alloys. The output of these plants is not included in the statements of refined-copper production in the preceding tables but is included in the following statement of secondary-copper production.

Copper sulphate.—The production of hydrous copper sulphate or bluestone by copper refineries in the United States was 36,444,550 pounds having a copper content of 9,283,000 pounds in 1936 compared with 26,507,526 pounds having a copper content of 6,752,000 pounds in 1935.

The output of copper sulphate by plants other than the regular primary refineries was 33,962,947 pounds with a reported copper content of 8,626,000 pounds in 1936 compared with 35,887,265 pounds containing 9,136,000 pounds of copper in 1935.

The increase in production at regular primary refineries more than offset the drop at other plants.

SECONDARY COPPER

Secondary copper includes material recovered from remelting old copper and copper scrap and from the treatment of copper alloys or alloys treated without separation of the copper. The following table summarizes the production of secondary copper during the past 5 years. Further details appear in the chapter on Secondary Metals.

Secondary copper produced in the United States, 1932-36, in short tons

	1932	1933	1934	1935	1936
Copper as metal.....	140,500	193,100	220,400	270,000	260,000
Copper in alloys.....	107,680	145,000	157,000	178,900	224,600
Total secondary copper.....	248,180	338,100	377,400	448,900	484,600
From new scrap.....	67,200	77,800	66,500	87,200	101,900
From old scrap.....	180,980	260,300	310,900	361,700	382,700
Percent of domestic mine output.....	104	177	159	118	81

The production of secondary copper in 1936 increased only 8 percent, whereas the output of copper by the mines was 58 percent larger. In consequence, the ratio of secondary to primary production fell from 118 percent in 1935 to 81 in 1936, a continuation of the decline from 177 percent in 1933, when the rate of activity at domestic copper mines was at an extremely low level. It is reasonable to assume that

the ratio will decline further in the near future, although the long-time trend indicates that secondary copper is supplying a steadily increasing proportion of our total copper output. In 1910 secondary copper was equivalent to less than 20 percent of the domestic mine output, whereas in 1929 it was 63 percent.

CONSUMPTION AND USES

New supply.—The total available supply of new copper consists of the total output of primary copper by refineries plus the imports of refined copper; in 1936 it amounted to 1,654,540,642 pounds, an increase of 36 percent over 1935. (See table on p. 153). If this figure is reduced by the quantity of refined copper exported and adjusted for changes in stocks at refineries, the quantity of new copper made available for domestic consumption may be estimated. This computation is made in the table that follows. It should be noted, however, that exports and stocks include some refined secondary copper that cannot be determined separately and that actual consumption of new copper would differ from the figures shown in the table by the changes in consumers' stocks on which data are not available.

New refined copper withdrawn from total year's supply on domestic account, 1932-36, in pounds

	1932	1933	1934	1935	1936
Total supply of new copper.....	848,661,722	752,441,910	945,553,301	1,213,753,468	1,654,540,642
Stock at beginning of year.....	924,600,000	1,004,000,000	813,000,000	569,000,000	350,000,000
Total available supply.....	1,773,261,722	1,756,441,910	1,758,553,301	1,782,753,468	2,004,540,642
Copper exported ¹	250,058,954	264,742,586	544,276,582	550,012,320	472,182,922
Stock at end of year.....	1,004,000,000	813,000,000	569,000,000	350,000,000	220,000,000
	1,254,058,954	1,077,742,586	1,113,276,582	900,012,320	692,182,922
Withdrawn on domestic account.....	519,202,768	678,699,324	645,276,719	882,741,148	1,312,357,720

¹ Includes refined copper in ingots, bars, rods, or other forms.

As shown in the foregoing table, the quantity of new copper withdrawn on domestic account in 1936 was 49 percent above that in 1935 and 26 percent below that in the record year 1929.

Total supply.—Adding 969,200,000 pounds of secondary copper and copper in alloys produced during the year to the 1,312,400,000 pounds of new refined copper withdrawn on domestic account gives a total supply of 2,281,600,000 pounds of new and old copper available for domestic consumption in 1936. The secondary copper, however, includes remelted new scrap as well as old scrap. The new scrap represents a revolving supply required in manufacturing, so that a more significant figure of supply available for domestic consumption is obtained by adding to the new refined copper only the secondary copper derived from old scrap (765,400,000 pounds). The total available for consumption by this calculation would be 2,077,800,000 pounds in 1936 compared with 1,606,000,000 pounds in 1935 and 2,587,000,000 in 1929.

Industrial use of copper.—The American Bureau of Metal Statistics estimates the actual consumption of new and old copper in the United States by uses. Data for the past 5 years are shown in the accompanying table.

Estimated use of copper in the United States, 1932-36, in short tons

	1932	1933	1934	1935	1936

	368,000	415,000	463,000	574,700	749,000

¹ Generators, motors, electric locomotives, switchboards, light bulbs, etc.² Transmission and distribution wire and bus bars; accounting only for the public utility companies.³ Does not include starter, generator, and ignition equipment.⁴ Excludes electrical work.⁵ Bearings, bushings, lubricators, valves, and fittings.⁶ Includes air conditioning, beginning with 1933.⁷ Exclusive of electrical equipment.⁸ Other than railway.

The foregoing table indicates that the use of copper in 1936 increased 30 percent over that in 1935, with virtually all items sharing in the improvement, but that the total still was 35 percent below consumption in 1929. Electrical manufactures increased 28 percent over those of 1935 but were 37 percent below those in 1929. Telephones and telegraphs gained 44 percent in 1936, but made one of the poorest showings in relation to 1929, having fallen 84 percent from that year. Light and power lines were 30 percent above 1935 but 43 percent below 1929. Other wire fared much better, with consumption in 1936 88 percent above 1935 and only 15 percent below 1929. Automobiles, exclusive of starter, generator, and ignition equipment, took 14 percent more copper than in 1935 but 22 percent less than in 1929. The best showings of the year were made by building and radio uses, which made new high records in 1936. Building, exclusive of electrical work, used 45 percent more copper in 1936 than in 1935 and 20 percent more than in 1929. Radio receiving sets used 50 percent more copper than in 1935 and 55 percent more than in 1929.

STOCKS

The following table gives domestic stocks of copper reported by smelters and refineries.

Stocks of copper in the United States, Jan. 1, 1930-37, in pounds

Year	Refined copper	Blister and materials in process of refining	Year	Refined copper	Blister and materials in process of refining
1930.....	306, 000, 000	500, 000, 000	1934.....	813, 000, 000	388, 000, 000
1931.....	615, 000, 000	450, 000, 000	1935.....	569, 000, 000	389, 000, 000
1932.....	924, 600, 000	348, 000, 000	1936.....	350, 000, 000	472, 000, 000
1933.....	1, 004, 000, 000	378, 000, 000	1937.....	220, 000, 000	391, 000, 000

Stocks of refined copper at refineries in the United States declined sharply in 1936 and were the smallest recorded since the end of 1928, according to reports submitted to the Bureau of Mines. They were only 22 percent of the record stocks on hand at the end of 1932. Stocks of blister copper and of materials in process of refining also were lower than for 1935 but were somewhat higher than the quantities on hand at the end of 1932, which, however, were not record stocks for this class. The decline in stocks of refined copper in 1936 was due mainly to the excess of apparent domestic consumption over production and to the increase in exports of domestic copper in that year. What portion of stocks at refineries may have been transferred to consumers' plants cannot be determined, as data covering consumers stocks are not available.

Figures of the Copper Institute, quoted in the press, indicated that world stocks of copper declined from 485,000 short tons at the beginning of 1936 to 353,000 at the close of the year. The former figure comprised 231,000 tons held in the United States and 254,000 tons held elsewhere. At the end of 1936 the United States held 161,000 and the rest of the world 192,000 tons. Thus, according to this authority, stocks of refined copper in the United States declined 30 percent, whereas those of the rest of the world fell 24 percent. The figures for the United States presumably include some metal held by or for consumers, as reports to the Bureau of Mines from refineries indicate that producers' stocks of refined copper, as shown in the preceding table, were 175,000 and 110,000 tons, respectively, at the beginning and end of 1936.

PRICES

Reports to the Bureau of Mines from copper-selling agencies in the United States indicate that 1,535,000,000 pounds of copper were delivered to domestic and foreign purchasers in 1936 at an average price (f. o. b. refinery) of 9.2 cents per pound. These deliveries are exclusive of copper produced and delivered outside of the United States. The average price for 1936 was 0.9 cent higher than that received in 1935 and nearly 3 cents higher than that for 1932, the lowest on record.

The average quoted monthly price for electrolytic copper, domestic f. o. b. refinery, according to the Engineering and Mining Journal, remained at 9.025 cents a pound throughout the first quarter of the year. In response to record-breaking sales, the price began to advance in April at a comparatively slow pace and averaged 9.525 cents for August and September. The upward movement of prices was considerably sharper in the final quarter of the year, and the average for December was 10.76 cents. On December 31 the price stood at 11.775 cents, and the forward surge that carried it to that level swept

it upward to 16.775 cents a pound on March 31, 1937. The movement of prices in the last months of 1936 and early in 1937 is to be contrasted with the relatively minor variations in copper quotations from the second quarter of 1933 through the third quarter of 1936.

One of the outstanding features of the price situation in 1936 was the return of the domination of the London price over the domestic price. As will be noted from the accompanying table, beginning with September, the average London price for copper was higher than the domestic price, despite the tariff of 4 cents a pound on metal imported. The price increases in the United States from then on followed rapid advances in the London market.

Average monthly quoted prices of electrolytic copper for domestic and export shipments, f. o. b. refineries, United States, and for spot copper at London, 1935-36, in cents per pound

FOREIGN TRADE ²

United States imports and exports of copper constitute a well-balanced trade, through which the smelting, refining, and manufacturing facilities of this country are utilized to treat foreign raw materials and to return refined copper and manufactures of copper abroad.

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Ninety-seven percent by weight of the copper imported in 1936 was contained in ore, concentrates, and unrefined furnace products. Much of the remainder—probably most of it—though already refined, consisted of ingots to be remelted and recast in the United States. By contrast, 94 percent of the exports consisted of refined copper and primary manufactures therefrom.

Separation of total exports to show the quantity of domestic copper shipped from the United States is not possible. Data at hand, however, indicate that much more domestic metal was exported in 1936 than in 1935, the excess of total exports over imports of unmanufactured copper being 144,000,000 pounds in 1936 compared with 91,000,000 pounds in 1935. In addition to the copper shown in the accompanying tables, an unrecorded quantity of metal is exported in manufactures, such as electrical machinery.

Imports.—Total imports of unmanufactured copper fell 26 percent—from 514,000,000 pounds in 1935 to 381,000,000 pounds in 1936. The major part of the decline was in receipts of unrefined copper, which were 120,000,000 pounds less than in 1935. Lower receipts of unrefined copper from Canada, Mexico, and Chile were mainly responsible for the drop in imports of this class. Imports of copper in the form of ore and concentrates were larger in 1936 than in the preceding year. Refined copper, imported chiefly from Chile, dropped from 36,142,671 pounds in 1935 to 9,563,232 pounds in 1936.

Exports.—Exports of copper of all classes totaled nearly 525,000,000 pounds in 1936. The exports were thus 13 percent below those for 1935 but, because of the larger drop in imports, actually indicate an increase in net exports of copper. Lower exports of refined copper bars and ingots, the most important class, were mainly responsible for the drop in the total.

Most of the copper shipped from the United States goes to Europe. Exports to France and Germany were 86,000,000 and 80,000,000 pounds, respectively, increases from 65,000,000 pounds for each country in 1935. Quantities shipped to United Kingdom and Italy dropped sharply from 110,000,000 and 91,000,000 pounds, respectively, to 62,000,000 and 48,000,000 pounds. Shipments to Japan also fell abruptly, from 110,000,000 pounds in 1935 to 80,000,000 in 1936.

WORLD ASPECTS OF COPPER INDUSTRY

International cooperation.—As indicated in Minerals Yearbook, 1936, the international curtailment agreement, which embraced the larger copper producers outside of the United States, was renewed in April 1936 to run until July 1, 1938. It was largely owing to this agreement that production declined or was relatively stationary in most of the important producing countries. The notable increase in production in the United States in 1936 was chiefly responsible for the increase in world output in that year. Under the agreement output rates were raised five times in the latter part of 1936, beginning August 1, to meet increasing demands for the metal. Members of the agreement were operating at 70 percent of their quota basis (far below actual capacity) through July. The production rate was increased 5 percent each on August 1, October 1, and October 15, and 10 percent each on November 1 and November 5, so that at the end of the year producers were operating at 105 percent of their quota basis. Early in January 1937 all restrictions on production were removed in an effort to satisfy consumption and speculation demands.

World smelter production.—World smelter production increased 18 percent in 1936 mainly because of the large gain in output in the United States, although there was an increase of 5 percent in output outside of the United States. United States smelter production from domestic ores was 60 percent larger in 1936 than in 1935 but amounted to only 61 percent of the total for 1929, whereas the output of the remainder of the world increased 5 percent in 1936 and was 133 percent of that for 1929. Thus, despite the large gain in production in the United States in 1936, United States smelter output has declined sharply in relation to the world total since 1929. In the countries that stood next to the United States in importance in 1936, production in Chile, Canada, and Rhodesia fell 6 percent, 1 percent, and 1 percent, respectively. The outputs of Chile and Canada, however, were 81 and 239 percent of their 1929 totals, while Rhodesia's tonnage in 1929 was insignificant. The comparison would doubtless have been more unfavorable to the United States had it not been for the international curtailment agreement. Smelter production increased in Japan U. S. S. R. (Russia), Germany, and Peru in 1936, the increase in U. S. S. R. being of notable proportions.

World smelter production of copper, 1932-36, in metric tons

¹ In addition to the countries listed, copper is smelted in Turkey, but data of output are not available.² Copper content of blister produced.³ Approximate production.⁴ Smelter output from domestic and foreign ores, exclusive of scrap. The production from domestic ores only, exclusive of scrap, was as follows: 1932, 246,757 tons; 1933, 204,115 tons; 1934, 221,558 tons; 1935, 345,902 tons; 1936, 554,659 tons.⁵ Figures represent blister copper only. In addition to blister copper, Belgium reports a large output of refined copper which is not included above as it is believed produced principally from crude copper from the Belgian Congo and would, therefore, duplicate output reported under the latter country.⁶ Data not yet available.⁷ Exclusive of material from scrap. (Metallgesellschaft, Stat. Zusammenstell.)⁸ Smelter output from ores.⁹ Exclusive of material from scrap.¹⁰ Approximate production. (Imp. Inst., London.)¹¹ Output from U. S. S. R. in Asia included under U. S. S. R. in Europe.¹² Exports of ingots and slabs.¹³ Less than 1 ton.¹⁴ Approximate production, based on the output of the countries shown, which in 1935 contributed nearly 83 percent of the total world output.

World mine production.—Statistics of mine production are of interest, as they show the original sources of the world supply of copper more accurately than smelter figures. The following table, which shows mine production during the past 5 years, is compiled largely from official data, many of which are not yet available for 1936.

World mine production of copper, 1932-36, in metric tons

¹ Approximate production.² Copper content of exports.³ Data not yet available.⁴ Smelter product.⁵ Output from U. S. S. R. in Asia included under U. S. S. R. in Europe.⁶ Fine copper content of smelter output.⁷ Year ended Mar. 31 of year following that stated.

World consumption.—World consumption of copper in 1936 is estimated by the American Bureau of Metal Statistics at 2,072,000 short tons, an increase of 15 percent over 1935 and, with the exception of 1929, the highest on record. Had the use of copper in the United States equaled that in 1929, the world total would have been consider-

ably above that for 1929. According to the authority mentioned, consumption in the United States increased 40 percent in 1936 but was 28 percent below the record for 1929. Copper used in the remainder of the world in 1936 was 4 percent above the record consumption for 1935 and 32 percent larger than in 1929. Greater use of copper was evident in all of the major consuming countries of the world except Germany, Japan, and Italy. Germany's consumption was reduced by substitution and by Government restriction of the use of copper to necessities. The reduction in Italy followed a record year of use in 1935 and coincided with the termination of war between Italy and Ethiopia. The decline in Japan may be explained by the increased use of scrap material, although consumption in Japan is far above the record for years prior to 1935 despite the drop in 1936. U. S. S. R. (Russia), which ranked seventh as a consumer in 1929, stood fourth in 1936, increasing the quantity used 151 percent in 1936 over that used in 1929.

REVIEW BY COUNTRIES

Belgian Congo.—Production in Belgian Congo continued at a curtailed rate in 1936 owing to the international restriction agreement. Productive capacity of Union Minière du Haut-Katanga is reported as 200,000 tons of copper, but output under the agreement totaled only 107,682 metric tons in 1935. Up to the end of 1935 about 1½ million tons of metal had been produced³ from 25 million tons of ore, and the shareholders had received £7,000,000 in dividends. The principal concentrator is at Panda, and the smelter is at Lubumbashi, near Elisabethville. When the article was written an electrolytic leaching plant had just recently begun to operate at Panda to treat lower-grade sulphide ores. Refining of Union Minière copper is done at the two plants of the Société Générale Métallurgique de Hoboken in Belgium, one at Hoboken, near Antwerp, and the other at Oolen, in Belgian Limberg. At the latter place there is an electrolytic refinery of 110,000 tons annual capacity.

Canada.—Smelter production of copper in 1936 totaled 191,155 short tons, slightly under the record output of 193,420 tons in 1935, while the mine total of 210,461 tons was a little higher than the previous record output of 209,499 tons in 1935. Ontario mines contributed 68 percent of the mine total, Quebec 16 percent, Manitoba and Saskatchewan together 11 percent, and British Columbia 5 percent. Production in 1935 and 1936 is shown by Provinces in the following table:

Copper produced (mine output) in Canada, 1935-36, by Provinces, in pounds

	1935	1936		1935	1936
British Columbia.....	38, 478, 043	21, 067, 501	Quebec.....	79, 050, 906	66, 340, 175
Manitoba.....	38, 011, 371	29, 853, 220	Saskatchewan.....	11, 429, 462	14, 971, 609
Nova Scotia.....		779, 307			
Ontario.....	252, 027, 928	287, 910, 908		418, 997, 700	420, 922, 720

Output in Ontario and Saskatchewan improved, but that in other districts declined. Nova Scotia produced a small quantity in 1936

³ South African Mining and Engineering Journal, The Copper Belt of Central Africa: Vol. 47, no. 2269, July 25, 1936, p. 729.

compared with none in 1935. All the Ontario output is derived from the nickel-copper ores of the Sudbury district and consists of copper in converter copper made by International Nickel Co., Ltd., and of copper in copper matte exported by that company and the Falconbridge Nickel Mines, Ltd. The Copper Cliff smelter of International Nickel, whose capacity was increased one-third in 1936, produced 139,796 tons of blister copper, and 137,012 tons of refined copper were produced by the refining subsidiary, Ontario Refining Co., Ltd. New developments of importance were the installation of a 30-ton arc-type electric melting furnace and a scheme for transporting molten blister copper from the Copper Cliff smelter to the refinery, a distance of about 1 mile. The company claims that many costly steps from the smelter converters to the refinery anode furnaces are thus eliminated. Copper is secondary to nickel in International's operations, representing about 30 percent of the combined value of production of the two metals. The output of Quebec is mainly from Noranda, which lowered its production from 37,239 tons in 1935 to 31,375 tons in 1936. The Flin Flon mine, on the boundary between Manitoba and Saskatchewan, is entirely responsible for the output of these two Provinces. Preparations were under way for the reopening of the Sherritt-Gordon mine in Manitoba in 1937. After the closing of the Granby mine in August 1935, the Britannia mine at Howe Sound was the only important producer in British Columbia. In 1936 Granby began preparations for reopening its Copper Mountain mine, and this property is expected to come into production in 1937.

Canada exports a large part of its copper. In 1936, shipments included 23,000 tons of copper in ore, matte, etc., 155,000 tons of refined products, and 24,000 tons of rolled products. The United States was the principal recipient of the ore and matte. The United Kingdom took 69 percent of the refined copper.

Chile.—Copper production in 1936 totaled 244,664 metric tons, 15,266 tons less than in 1935, owing to the fact that Chilean producers were operating under the world production-curtailment agreement. Chile Copper produced 112,000 metric tons compared with 119,700 tons and Andes 27,000 tons compared with 26,000 tons. Braden produced 92,600 tons from ore having an average copper content of 2.19 percent compared with 101,600 tons in 1935. At Braden a monthly production rate of 7,683 short (7,000 metric) tons was maintained through July. Beginning with August, progressive increases were made until output reached an average of 11,525 short (10,500 metric) tons in November and December.

France.—France ranked sixth in copper consumption in the world in 1936, but it produces only an insignificant amount of either ore or metal. Consumption totaled 113,000 metric tons, an increase of 7 percent over the quantity used in 1935. In 1936 imports of unmanufactured copper totaled 118,000 tons compared with 105,000 tons in 1935. Of the 1936 total, 100,000 tons were refined and 18,000 tons unrefined copper. Chile supplied nearly 39,000 tons of the refined total and the United States, Belgium, and Canada 18,000 to 20,000 tons each.

Germany.—Germany's attempts to decrease the consumption of imported metals by substitution and restriction met with some success in 1936. While the consumption of copper in virtually all other large consuming countries either increased or was maintained at previous high levels, Germany consumed 25,000 metric tons (12 percent) less

copper than in 1935, the only decrease of any consequence in the world. According to Wright,⁴ Germany has continued to operate the Mansfeld copper mines at a loss and thus supplied about one-tenth of her domestic copper requirements. German smelter output of copper in 1936 was 59,000 metric tons compared with 56,000 tons in 1935. Normally, more than half of the smelter output is from imported crude materials. Imports of metal fell from 153,000 tons in 1935 to 127,500 in 1936, of which more than half came from Belgian Congo and other Africa. Imports of foreign ores increased from 401,000 tons in 1935 to 482,000 in 1936, and of copper scrap from 20,000 to 24,000 tons.

Japan.—Smelter production of copper in Japan amounted to 78,114 metric tons, an increase of 10 percent over output in 1935. Although Japan was formerly self-sufficient with respect to its copper requirements and imported less than 300 tons in 1932, it imported 65,000 tons in 1935 and 48,000 in 1936. Japan's consumption of copper was reported to have declined to 127,500 tons in 1936 from the record-breaking total of 133,500 tons for 1935.

Mexico.—Smelter production is reported to have dropped from 41,200 metric tons in 1935 to about 28,000 tons in 1936, a continuation of the decline from 47,100 tons in 1934. Mine output was 39,373 tons in 1935 and fell to 29,713 tons in 1936. Boleo produced 7,095 tons in 1936 compared with 7,865 in 1935 and Cananea (Anaconda) 14,700 tons compared with 19,100. The Cananea property was closed down 2½ months early in 1936 because of labor difficulties. The Moctezuma mine of Phelps Dodge, idle since 1932, continued on a nonoperating basis in 1936.

Peru.—The Cerro de Pasco Copper Corporation reported the production of 71,482,061 pounds (32,424 metric tons) of copper in 1936, 12,640,051 ounces of silver, 45,087 ounces of gold, 19,620,151 pounds of lead, and 17,515 short tons (15,900 metric tons) of zinc concentrates. Production of the company in 1935 was 63,977,630 pounds (29,020 metric tons) of copper, 11,891,846 ounces of silver, 28,637 ounces of gold, 16,358,860 pounds of lead, and 16,174 short (14,700 metric) tons of zinc concentrates.

Northern Rhodesia.—Copper production in 1936 (144,617 metric tons) was slightly lower than the record output of 145,804 tons in 1935, because the producing companies were operating under the international curtailment agreement. The rate of production was speeded five times in the latter part of the year, beginning with August 1, in line with increases permitted by the members of the restriction agreement.

The Rhokana Corporation, Ltd., produced 50,399 long tons of copper in the year ended June 30, 1936; 25,057 tons was in the form of blister copper and 25,342 tons electrolytic copper. The average cost of production of blister copper was £22.345 and of electrolytic copper £25.346 a ton. These costs are exclusive of depreciation and debenture interest. Production in 1936 was, as usual, principally from the Nkana mine, where 1,564,564 short tons of ore carrying 3.775 percent copper were hoisted. The tonnage produced at the Mindola mine in connection with development work was 201,610 tons of an average grade of 3.617 percent copper. A recalculation of ore reserves resulted in estimates of 125,674,435 short tons of 3.50-percent copper ore for the Nkana mine and 143,780,000 tons of 4.66-percent ore for Nchanga

⁴ Wright, Chas. Will, *Germany's Nonferrous Mineral Industries: Special Suppl. 3, Mineral Trade Notes*, Bureau of Mines, Sept. 19, 1936, p. 2.

mine. The estimate for Nkana includes reserves for the Mindola mine and that for Nchanga is unchanged from former estimates.

The refinery at the Nkana plant of Rhokana, completed in 1935, has been described by Wheeler and Eagle.⁵

A new subsidiary of the Rhokana Corporation, Nchanga Consolidated Copper Mines, Ltd., has been formed for the purpose of acquiring and developing the Nchanga and Chingola mining grants as well as certain contiguous mining grants. Since November 1936, preliminary work in connection with the dewatering of the properties and reconditioning of the plant has been proceeding.

The production of blister copper for Roan Antelope for the year ended June 30, 1936, amounted to 50,672 long tons compared with 67,316 long tons in the previous year. The company reported revenue from copper sales as £34,581 per long ton for the fiscal year 1936 compared with £27,926 for 1935 while costs, including debenture interest and depreciation, increased, owing to the restricted rate of production, from £23,174 in 1935 to £24,773 in 1936. The company estimated reserves of ore at the end of the fiscal year as 95,637,987 tons, containing an average of 3.43 percent copper.

The blister-copper production for the account of Mufulira amounted to 28,123 long tons for the year ended June 30, 1936, compared with 20,723 tons for the previous year. The average revenue from copper sales increased from £27,908 per long ton of blister in 1935 to £35,166 in 1936 while costs, including debenture interest and depreciation, declined from £33,141 to £30,281. The Mufulira smelter was almost completed when the fiscal year ended and was reported to be in operation early in 1937. Its estimated maximum capacity is reported as about 100,000 long tons of copper a year. The company estimated reserves at the end of June 1936 at 114,390,000 short tons of ore containing 4.39 percent copper in the Mufulira mine; 25,000,000 tons of 3.46-percent ore in the Chambishi mine; and 21,000,000 tons of 3.47-percent ore in the Baluba mine, a total of 160,390,000 tons, averaging 4.12 percent.

U. S. S. R. (Russia).—The mine production of Russia places it first in Europe as a source of copper. In smelter output in the past 2 years it has ranked second to Belgium, which imports all of its crude materials. Smelter output in 1936 was 77,600 metric tons, compared with 63,247 tons in 1935. According to the Metal Bulletin,⁶ official Soviet estimates place copper reserves of the Soviet Union at 17,000,000 tons of copper.

Yugoslavia.—Mines de Bor, operated under French control, make Yugoslavia the second largest source of mine production of copper in Europe. The mine total for 1935 was 41,700 metric tons, but final data are not yet available for 1936. Smelter output was 39,400 tons in 1936 compared with 39,000 in 1935. A large part of Yugoslavia's crude copper has been refined in the United States. The company, however, plans to erect an electrolytic refinery in Yugoslavia to refine its own copper in the future.

The lead industry made further strides in 1936 in response to the marked recovery in industrial activity. Production, consumption, and prices were substantially above those in 1935, and considerable progress was made in liquidating the huge stocks accumulated during the depression. In short, the industry enjoyed its best year since 1931. A feature of 1936 was the notable increase in the use of lead in cable covering and building, although improvement in these industries still lags far behind that in other important industries using lead.

Salient statistics of the lead industry in the United States, 1925-29 (average) and 1932-36, in short tons

	1925-29 (average)	1932	1933	1934	1935	1936

¹ Revised figures.

² Data for 1934-36 include lead imported for immediate consumption plus material entering the country under bond as do figures for earlier years.

³ Subject to revision.

¹ This report deals primarily with the smelting, refining, and consuming phase of the industry. For full details of mining operations see separate reports issued for the various States.

Virtually all gains in 1936 were made in the second half of the year. From January to July domestic shipments failed to maintain the level established during the closing months of 1935, and in consequence stocks increased. Despite this, however, the price advanced from 4.50 cents a pound (New York) at the beginning of the year to 4.60 cents toward the end of February. This quotation held until October. Beginning in July demand became stronger not only in the United States but in Europe, where speculative buying in anticipation of the enormous rearmament program announced by the British Government was a leading factor. London prices reacted immediately, but the New York quotation did not advance appreciably until the last of October. Although New York prices rose sharply during Novem-

FIGURE 26.—Trends in the lead industry in the United States, 1900-1936. Imports include lead in ore, base bullion, and refined lead; exports include refined lead.

ber and December London prices rose faster, and by December exceeded those in New York for the first time since the World War. The differential between London and New York moved from 1.20 cents per pound in favor of New York in June to 0.03 cent in favor of London in December. At times during December it would have been profitable to export domestic lead to Europe, but apparently little or no lead was exported. At the close of the year quotations were 6.03 cents in New York and 6.21 cents in London. Domestic shipments exceeded production during the last half of the year by 60,000 tons. Figure 26 shows trends in the domestic lead industry from 1900 to 1936.

At the end of 1936 stocks of refined lead on hand in the United States totaled about 165,000 short tons, or approximately a 3-month supply. Although this is considerably above normal, price movements in the latter part of 1936 showed that the stocks were strongly

held and did not necessarily constitute a serious hazard to reasonable price appreciation. Moreover, these excess stocks proved of real value to the industry early in 1937, as they were an important factor in preventing exorbitant prices, which most producers agree would have been detrimental to the industry in the long run.

Outside the United States recovery over 1935 in production and consumption was not so pronounced. For example, domestic production increased 23 percent, whereas that abroad increased only 1 percent. Consumption likewise was 20 percent higher in the United States and only 7 percent higher elsewhere. Compared with pre-depression levels, however, domestic consumption in 1936 lagged considerably, being approximately a third below 1929, whereas abroad it was 12 percent above. The more favorable London price in 1936 was due to the smaller stocks held abroad when the buying wave started, cessation of supplies from Spain due to the civil war, and threatened curtailment elsewhere on account of labor troubles.

Trends in lead consumption.—Figure 27 compares the trend in lead consumption from 1929–36 with that of copper and zinc and with the general index of industrial activity. It will be noted that general

FIGURE 27.—Trends in the consumption of copper, lead, and zinc compared with general index of industrial activity, 1929–36. Indexes shown for industrial activity computed from Federal Reserve Board series. Consumption data from American Bureau of Metal Statistics.

industrial activity and zinc consumption have recovered more than lead and copper consumption. Zinc consumption and industrial activity in 1936 were 92 and 88 percent, respectively, of the 1929 totals whereas lead and copper consumption were only 65 percent of the 1929 averages. The more favorable position of zinc is due primarily to the fact that most of the output is used in consumer goods, production of which has progressed rapidly with returning prosperity. On the other hand, lead and copper are used largely in durable goods, and the hesitancy with which capital has been invested in new plant and equipment has retarded the use of these metals, particularly in the utility and building fields.

The effect of slow recovery in the utility and building industries on consumption of lead is shown in figure 28. Lead-covered cable is used extensively in the communications field and normally is one of the most important uses for lead. In 1929 it ranked first, taking 220,000 tons (23 percent) of the total lead consumed in that year. This outlet for lead, however, was the hardest hit of any of the major lead-consuming industries during the depression. By 1933 the tonnage had

declined to 31,400, and since then has increased to only 61,400 tons; most of the advance was credited to 1936, in which year cable covering consumed 10 percent of the total. The use of lead in building likewise has slumped severely—from 96,000 tons in 1929 (10 percent of the total) to 22,000 tons in 1932 with a subsequent rise to only 40,000 tons in 1936. Consumption of lead for all other purposes, which include pigments, storage batteries, ammunition, foil, alloys, etc., has improved surprisingly; the tonnage used in 1936 was 81 percent of the 1929 total. These purposes took 84 percent of all the lead used in 1936 compared with only 67 percent in 1929. Obviously, however, full return of lead consumption to predepression levels requires substantial improvement in the building and utility fields.

FIGURE 28.—Comparison of trends in consumption of lead in cable covering, building, and other uses with total lead consumption, 1929-36. Data from American Bureau of Metal Statistics.

DOMESTIC PRODUCTION

Refined pig lead produced in the United States is derived from three main sources—domestic ore, foreign ore and base bullion, and secondary materials. The following table lists the production from each of these sources from 1927 to 1936.

Total pig lead produced in the United States, 1927-36, in short tons

Year	From domestic ores and base bullion	From foreign ores and base bullion	From secondary materials	Total
1927.....	668,320	128,210	119,000	915,530

¹ Revised figures.

PRIMARY LEAD

Refinery production.—Production of refined primary lead in 1936 increased 23 percent; it was equivalent to the production in 1905 but was 49 percent below the 1925-29 average. The production of lead

derived from domestic ores increased about 25 percent in 1936. Production from foreign ores and base bullion decreased 18 percent and was equivalent to only 11 percent of the 1929 output; it accounted for only 3 percent of the total output of refined primary lead.

Refined primary lead produced in the United States, 1929-36

Year	Production (short tons)				Sources (short tons)			Value

¹ The lead content of antimonial lead is excluded (see p. 176).

² Desilverized soft lead is excluded.

³ Includes lead derived from Missouri ores and other nonargentiferous ores.

⁴ Revised figures.

Source of primary lead.—Of the total refined lead produced in 1936, 97 percent was derived from domestic ores and 3 percent from foreign ores. Production from foreign ores decreased 17 percent in 1936. In 1928 more than 128,000 tons of foreign bullion were refined in the United States; in 1936 such refining virtually ceased. Details of the sources of lead derived from domestic ores are given in the section on Mine Production.

¹ Revised figures.

Antimonial lead.—Antimonial lead or hard lead is an important byproduct of the refining of base bullion, but the amount derived from this source is only a small part of the country's yearly production. The major part is derived from the smelting of antimonial-lead scrap,

and some is produced by mixing metallic antimony with refined soft lead.

Several lead-smelting plants operate on scrap materials exclusively. Production data from such plants are summarized in the chapter on Secondary Metals. A large quantity of hard lead scrap also is treated at primary smelters and refineries, and the production of antimonial lead at these plants is shown in the table that follows.

Antimonial lead produced at primary lead refineries, 1929-36

Year	Production (short tons)				Antimony content		Lead content by difference (short tons)			
	From domestic ore	From foreign ore	From scrap	Total	Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total

² Segregation discontinued.

SECONDARY LEAD

Recovery of secondary lead decreased 3 percent in 1936. Return of battery scrap for smelting and refining was 10 percent less than in 1935, and stocks of scrap were considerably lower at the end of the year. As the output of domestic refined primary lead was 25 percent higher, the ratio of secondary- to primary-lead production declined from the record high of 87 percent in 1935 to 68 percent in 1936. If lead consumption continues to increase, further declines in this ratio may be expected, as additional supplies of the metal will have to come largely from the mines. Further details on secondary-lead production in 1936 are given in the chapter on Secondary Metals.

LEAD PIGMENTS

Lead pigments manufactured in 1936 contained 220,096 tons of lead, an increase of 11 percent over 1935. Of the 1936 total, 204,997 tons were derived from refined pig lead, of which white lead accounted for 44 percent, litharge 40 percent, red lead 15 percent, and sublimed lead and orange mineral 1 percent. Sublimed lead and leaded zinc oxide are the principal pigments in which the lead content is derived from ores.

Lead in pigments,¹ 1929-36, by sources, in short tons

Year	Lead in pigments from—				Year	Lead in pigments from—			
	Domestic ore ²	Metal	Scrap	Total		Domestic ore ²	Metal	Scrap	Total

¹ Includes also lead recovered in zinc oxide and leaded zinc oxide.

² No pigments from foreign ore.

MINE PRODUCTION

Mine production of recoverable lead in 1936 was 373,986 tons, an increase of 13 percent over 1935; it was 44 percent below the average for 1925 to 1929. Missouri, Idaho, and Utah continued to be the principal sources and contributed 30, 24, and 19 percent, respectively, of the total production. Missouri's output (to which the Southeastern Missouri district contributed 108,422 tons), increased 13 percent over 1935, Idaho's 16 percent, and Utah's 10 percent. Production in the Tri-State district increased 11 percent and amounted to 10 percent of the 1936 total. Among the minor producers in the West, Montana, Arizona, and Colorado contributed larger tonnages in 1936 than in 1935. Production in Nevada and New Mexico was only slightly below that in 1935. Further details of production by mines, districts, and States can be found in the various State reports.

STOCKS

Lead stocks, as reported by the American Bureau of Metal Statistics, are shown in the following table. Stocks of refined and antimonial lead include metal held by all primary refiners and by most refiners of secondary material who produce common lead. Foreign lead refined in the United States and entered for domestic consumption is included.

Lead stocks at end of year at smelters and refineries in the United States, 1929-36, in short tons

	1929	1930	1931	1932	1933	1934	1935	1936
Refined pig lead.....	41,726	95,524	147,466	164,722	191,624	223,593	215,595	165,159

	110,893	158,744	217,989	263,296	295,704	313,869	314,033	246,311

Substantial progress was made in 1936 in liquidating the large stocks of refined lead accumulated from 1929 to 1934. The tonnage on hand at the close of the year was equivalent to about a 3-month supply at the average rate of domestic shipments during the last 4 months of 1936. Although stocks are considerably above normal, the large quantity of metal available for immediate delivery is strongly held and early in 1937 aided in preventing a run-away price situation when the speculative market reached its height.

Virtually no published data are available on stocks held outside of the United States. The British Metal Corporation, in its annual review of the lead industry issued in January 1937, stated that stocks were low (less than a 1.5-month supply). The extremely rapid rise in the London price precipitated by the speculative buying wave in the first few months of 1937 indicates that prompt supplies were far from plentiful.

DOMESTIC CONSUMPTION

New supply.—The following table shows the refined primary lead available for consumption from 1929 to 1936. The computation does not take into account variations in producers' stocks, and as these have changed considerably during the past 8 years the quantities shown do not indicate the true trend in the actual consumption of new lead. The supply available for consumption in 1936 was 20 percent greater than in 1935 but was equivalent to only 55 percent of the 1925-29 average. As total consumption of lead advanced 18 percent in 1936, it is evident that more of the increased demand was supplied by primary than by secondary metal.

Refined primary pig lead available for consumption in the United States, 1929 and 1931-36, in short tons

¹ Stocks of pigs, bars, etc., in bonded warehouse included with base bullion. (See table on p. 183.)

² Includes small quantities of foreign lead reexported.

³ Revised figures.

Consumption by uses.—Owing to the large return of secondary lead from lead-consuming industries, the total consumption of pig lead greatly exceeds the supply of new lead available. The following table gives the American Bureau of Metal Statistics estimate of the total consumption of lead by industries, 1929-36.

Lead consumed in the United States,¹ 1929-36, in short tons

Purpose	1929	1930	1931	1932	1933	1934	1935	1936

¹ Source: American Bureau of Metal Statistics. These estimates are for the total consumption of lead irrespective of whether its origin be primary or secondary. Antimonial lead is included.

The total industrial use of lead increased 18 percent in 1936 but was still 35 percent below the 1929 record. All major uses increased in 1936 over 1935, and percentage gains for cable covering and building showed up exceptionally well. Compared with 1929, however, these two uses still lag far behind. The increased use of lead in foil was due partly to greater use of lead-tin foil in cigar wrappings, for which it is especially suitable because of its resistance to corrosion from the alkalis in the tobacco. The added resistance to corrosion and strength of tellurium lead are increasing the use of this alloy.

To assist the consumer in obtaining lead products of standard quality, the Lead Industries Association has adopted a Seal of Approval, effective January 1, 1937. The seal is available to manufacturers whose products meet the standards set up by the association for lead pipe, lead traps, and bends.

PRICES

The two major markets for lead in the United States are New York and St. Louis; much of the lead produced in the United States is sold at prices based on quotations in these markets. The New York quotations are influenced to some extent by the lower prices usually prevailing on the London market, so that the New York price seldom exceeds the St. Louis price by as much as the freight differential, normally 0.35 cent a pound.

The New York quotation for lead in 1936 averaged 4.71 cents per pound, an increase of 16 percent over the 1935 average of 4.06 cents and 31 percent below the 1929 average of 6.83 cents. At the beginning of the year the price stood at 4.50 cents, where it remained until the latter part of February, when it was raised to 4.60 cents. Despite a substantial increase in stocks during the first 6 months and a subsequent decline following active buying in July, August, and September there was no further change in price until October, when domestic shipments approached predepression averages. From then until the close of the year the price was carried steadily upward by continued domestic consumption at high levels, threatened shortage of supplies by shut-downs due to strikes at some mines in the West, and the boom market in London. On December 31 the price was 6.03 cents, the highest since February 1930.

¹ St. Louis: Metal Statistics, 1937, p. 399. Average daily quotations of soft Missouri lead, f. o. b. St. Louis (open market), as reported daily in the American Metal Market.

New York: American Metal Market, daily issues. Pig lead, New York (outside market), prompt shipment from West.

London: Metal Statistics, 1937, p. 403. Average price of foreign lead. Price per long ton, as published in Metal Statistics, converted to cents per pound at average exchange rate reported by the Federal Reserve Board.

² London quotations in pounds sterling per long ton, as follows: 1933, £11.6708; 1934, £10.9333; 1935, £14.2375; 1936, £17.6000.

The London quotation for 1936 (United States exchange basis) averaged 3.91 cents per pound, the highest since 1930. The differential between New York and London in 1936 averaged 0.80 cent per pound in favor of New York. During the latter half of the year, however, the price advance in London was more pronounced than in New York owing to a more favorable stock position abroad, cessation of supplies from Spain caused by the civil war, and threatened curtail-

ment elsewhere on account of labor troubles. In consequence, London set the pace in the upward swing, and by December the London quotation actually exceeded the New York. At times the differential in favor of London was high enough to make exportation from the United States profitable. On December 31, the London quotation was equivalent to 6.21 cents per pound, compared to 6.03 cents at New York.

FOREIGN TRADE¹

The foreign trade of the United States in lead consists largely of imports of ore and base bullion, which are smelted and refined in bond, and the export of this lead either as refined lead or in manufactured products. Since 1927, however, this trade has declined. In 1936 only 23,615 short tons of lead in ore, base bullion, and refined and scrap lead were imported, compared with 161,389 tons in 1927; exports of refined lead decreased from 125,267 to 18,314 tons. During the same period lead exported in manufactures with benefit of drawback declined from 12,004 to 7,735 tons.

Imports.—Total imports of lead in ore and matte, including imports for immediate consumption and entries for warehouse, increased slightly. Larger receipts from Mexico, Canada, and Peru were offset by smaller shipments from Newfoundland and Chile. Imports of base bullion virtually ceased, but imports of refined lead, which for several years were only a few hundred tons, increased to 2,590 tons in 1936. Total imports of lead decreased 2 percent and were only 20 percent of the 1929 total.

Total lead imported into the United States, 1930-36, by classes, in short tons¹

Year	Lead in ore and matte	Lead in base bullion	Pigs, bars, sheets, and old	Total lead content

Exports.—Exports of refined lead nearly trebled in 1936, and Mexico and Japan imported virtually the entire increase. Exports credited to Mexico, however, probably represent shipments destined for other countries. Very little, if any, of the lead exported in 1936 was domestic metal.

TECHNOLOGY

Mining.—The lead industry advanced rapidly in the use of mechanical loading equipment. The mines of the Southeastern Missouri district are now virtually on a 100-percent mechanized basis, and many lead and lead-zinc mines in the Eastern and Western States are equipped with mechanical shovels and scrapers. A survey recently conducted by the Bureau of Mines³ indicates that there is much interest in mechanical loading and that such equipment has a large potential use.

Stope filling by means of a free-flowing mud dropped from the surface through raises has been adopted at the Sullivan mine in British Columbia. Excess water is drained off the bottom of the stope. The mud is expected to set sufficiently to permit easy mining of adjacent pillars.

Milling.—A total of 335,889 short tons of lead flotation concentrates was produced in the United States in 1936 (exclusive of the Tri-State and Wisconsin districts), according to the American Bureau of Metal Statistics. The average lead content was 59.28 percent compared with 60.19 percent in 1935 and 54.81 percent in 1929. According to Pallanch,⁴ modern flotation practice is governed largely by economic considerations and frequently high-grade metallurgical results are not justified under conditions imposed by smelter contracts, freight rates, and prices.

A new edition of Flotation Plant Practice by P. Rabone was published in 1936.

Smelting.—Of outstanding interest is the new volume on Metallurgy of Lead and Zinc issued early in 1937 as volume 121, Transactions of the American Institute of Mining and Metallurgical Engineers. The book presents a complete summary of the present status of lead metallurgy.

In reviewing the progress of lead metallurgy in 1936, Hayward⁵ points out that increasing supplies of precious-metal concentrates at some plants have so reduced the lead content of the charge that some bullion has to be recirculated to collect the precious metals. The advantages of a larger number of tuyères with smaller diameter, as demonstrated at Trail, British Columbia, have resulted in their use at other plants.

A unique process for the simultaneous production of lead and sulphur by electrolysis of galena is being tested in North Wales. In a semi-commercial plant 300 tons of lead 99.95 percent pure and 40 tons of sulphur 99.5 percent pure have been produced. The operation is conducted in what is described as a "fused chloro-sulphide melt." The principal advantage claimed for the process over smelting is that it eliminates the sulphur-disposal problem.⁶

Processes used in the recovery of lead from battery scrap and residues were described by Thews in the January 1937 issue of Canadian Chemistry and Metallurgy.

WORLD ASPECTS OF LEAD INDUSTRY

International cooperation.—The informal agreement of July 1935, under which certain producers agreed not to increase production

⁶ Chemical Engineering and Mining Review, vol. 29, no. 341, Feb. 8, 1937, p. 195.

without due notice to each other, apparently was continued in 1936. The latter part of the year the Lead Industries Development Council, an organization of British producers, established a Technical Information Bureau in London to promote the use of lead.

World production.—World smelter production of lead increased 6 percent in 1936 and was equivalent to 82 percent of the record output in 1929. Production increased 23 percent over 1935 in the United States and 1 percent elsewhere. The domestic output constituted only 57 percent of the 1929 total, whereas that of the rest of the world was 97 percent. The United States continued as the leading producer and contributed 25 percent of the 1936 total. The 10 other leading producing countries and the proportion of the world total each contributed in 1936 were as follows: Mexico 15 percent, Australia 13, Canada 11, Germany 10, India (Burma) 5, Belgium 5, U. S. S. R. (Russia) 3, Spain 3, Italy 3, and Tunisia 1. Of these, Australia, Spain, and Tunisia experienced substantial declines, whereas Mexico, Canada, Germany, and the U. S. S. R. (Russia) made notable increases. India and Belgium increased their production slightly in 1936, and Italy reduced her output moderately. Among the minor producers, the United Kingdom declined sharply, and Peru, Japan, and France increased their output appreciably. Production in the British Empire was about 450,000 metric tons in 1936, a decrease of 4 percent from 1935. The Empire share of world output was 31 percent in 1936 compared with 22 percent for the 5-year period, 1925–29.

³ Exclusive of secondary material (Metallgesellschaft, Frankfurt).

⁴ Approximate production.

⁵ Year ended Mar. 31 of year following that stated.

⁶ Year ended Sept. 30.

⁷ Figures cover lead refined from domestic and foreign ore; refined lead produced from foreign base bullion not included.

World consumption.—The American Bureau of Metal Statistics reports world consumption of lead in 1936 as 1,596,700 metric tons, an increase of 12 percent over 1935 and equivalent to 95 percent of the 1929 record. The increase in the United States over 1935, after allowance is made for changes in stocks and including secondary and antimonial lead produced at primary refineries, was 26 percent compared with 7 percent elsewhere. Compared with predepression levels, however, foreign consumption was relatively much higher, as it actually exceeded the 1929 total 12 percent, whereas the United States used 33 percent less. According to the American Bureau of Metal Statistics Spain was the only important consumer that used less lead in 1936 than in 1935, but later information indicates that apparent consumption in Italy declined about 33 percent owing to a decrease in imports, which were exceptionally high during the latter part of 1935. Since much of the lead imported in 1935 probably was used in 1936, actual consumption in 1936 may have been higher than that in 1935. Other important lead-consuming countries showed percentage increases as follows: United Kingdom 6, Germany 20, Japan 8, France 2, U. S. S. R. (Russia) 19, and Belgium 12. The United States, which used 28 percent of the total quantity of lead consumed in 1936, again ranked first in consumption. The other leading consumers and the percentage of the total each absorbed in 1936 were as follows: United Kingdom 22, Germany 13, Japan 7, France 6, U. S. S. R. (Russia) 5, Italy 4, and Belgium 3.

REVIEW BY COUNTRIES

Australia.—The 11-percent decrease in smelter output in 1936 was due to a decline in production of lead at Port Pirie. The 1935 output at this plant was unusually large owing to the smelting of stocks of ore accumulated in previous years.

Crude ore raised from the Broken Hill mines in 1936 totaled 1,350,000 long tons, an increase of 42,700 tons over 1935. Production of lead concentrates increased from 243,800 long tons in 1935 to 256,000 in 1936. In addition to the four principal producers, Broken Hill Proprietary Co., Ltd., resumed operations in March after a shutdown of several years. The British section of the North mine was put into operation in August. A new treatment plant, with a monthly capacity of 50,000 tons of ore, will be installed at the North mine.

Output of lead bullion from Mt. Isa increased from 33,100 tons in 1935 to 35,382 tons in 1936. During the year an application was made to the Commonwealth for a concession to build a railway from Mt. Isa to the Gulf of Carpentaria, thereby reducing the rail haulage from 603 miles to 200 or 300 miles.

The new smelting plant of Wiluna Gold Mines, Ltd., at Wiluna, Western Australia, for the treatment of antimonial-lead flotation concentrates, made its first run on October 2. The plant has been described by Ling.⁷

Exports of pig lead from Australia declined from 189,000 tons in 1935 to 176,000 tons in 1936, and shipments of ore and concentrates increased from 18,000 to 31,000 tons. Both metal and ore are sold chiefly in the European market.

⁷ Ling, E. S., Wiluna Gold Mines Smelting Plant; Canadian Min. Jour., vol. 58, no. 5, 1937, pp. 235-240.

Belgium.—Refined lead production in Belgium is derived from foreign ores and base bullion. In 1936, 99,900 metric tons of lead ores and 35,200 tons of pig lead were imported. Yugoslavia, Sweden, Canada, South America, and Australia were the principal sources of the ore, and Mexico supplied most of the pig lead. Imports of ore were 17 percent more than in 1935 and imports of metal 55 percent more. About 57,000 tons of pig lead and 8,000 tons of lead in sheets, pipe, etc., were exported in 1936.

Canada.—Mine production of lead in Canada in 1936 was 191,400 short tons, an increase of 13 percent over 1935. British Columbia produced 98 percent of the total, with Yukon and Northwest Territories, Quebec, and Nova Scotia contributing about 1,000 tons each. At the Sullivan mine of the Consolidated Mining & Smelting Co., Ltd., the principal producer in British Columbia, the concentrator treated 1,901,000 short tons of ore which yielded 253,154 short tons of lead concentrates; 227,000 tons were produced in 1935. Production at the Trail smelter, the only active lead smelter in Canada, reached an all-time high and costs an all-time low. Lead recoveries were slightly lower than in 1935. The Tetreault mine in Quebec made the entire output from that Province, the Stirling mine that from Nova Scotia, and the Mayo camp that from Yukon.

Exports of refined pig lead amounted to 161,000 short tons compared with 141,000 tons in 1935; the United Kingdom took 100,000 tons and Japan 49,000 tons of the 1936 total. Shipments to the United Kingdom were 7 percent higher and those to Japan 42 percent higher than in 1935. Exports of lead in ore dropped from 5,700 to 4,700 short tons.

France.—France ranks fifth in lead consumption and depends largely on foreign lead for its supply. Consumption was 93,100 metric tons in 1936, an increase of 2 percent over 1935. Imports of refined pig lead declined from 82,000 metric tons in 1935 to 79,500 tons in 1936. In addition, 6,100 metric tons of bullion were imported in 1936 compared to 3,600 tons in 1935. The principal sources of refined and crude lead in 1936 were Spain, 26 percent; Belgium and Tunisia, 23 percent each; and Mexico, 20 percent. More than 40,000 metric tons of lead ore were imported in 1936 compared with 7,000 tons in 1935, and 9,600 tons were exported. Other lead exports were relatively unimportant.

In October the French Government suspended subsidies to lead mines, owing to the substantial rise in prices. Operation of the Pennarroya smelter at Noyelles-Godault was begun in October. Its initial capacity is stated to be 40,000 metric tons of metal a year, and an increase to 60,000 tons is contemplated.

Germany.—Consumption of lead in Germany increased from 172,000 metric tons in 1935 to 207,000 in 1936; most of the increase was due to the rise in smelter output. Imports of pig lead were 69,000 tons, of which Mexico supplied 40,000 tons. Exports declined from 4,000 tons in 1935 to 1,000 in 1936. Imports of lead ore amounted to 99,000 tons compared with 84,000 in 1935. Newfoundland, Yugoslavia, South America, Australia, and the United Kingdom were the principal sources. Apparently domestic mines supplied only 60 percent of the smelter output in 1936. Lead mining is conducted under Government subsidy, and the use of lead is rigidly restricted by Government rulings.

Greece.—The Compagnie Française du Laurium produced 4,172 metric tons of lead in 1936 compared with 4,692 tons in 1935.

India, British.—The Burma Corporation, Ltd., produced 104,280 long tons of lead concentrates containing 66 percent lead and 46 ounces of silver per ton compared with 106,000 long tons containing about 65 percent lead and 43 ounces of silver per ton in 1935. The output of refined lead was 71,915 long tons compared with 70,560 tons in 1935; 1,240 long tons of antimonial lead were also produced. Exports of refined and antimonial lead totaled 70,000 long tons, of which the United Kingdom took 47,000 and Japan 12,000 tons.

Italy.—Although lead production has increased at Italian mines in recent years, Italy still depends on foreign lead to a considerable extent. Production of lead concentrates totaled 49,875 metric tons in 1936, imports 21,571 tons, and exports 4,600 tons, indicating a net consumption of 66,846 tons for the year. Thus, net imports accounted for 25 percent of the total lead consumed. Production of metal amounted to 40,500 metric tons, and net imports were 8,000 tons which was 16 percent of the apparent consumption of 48,500 tons. Since 25 percent of the smelted product was derived from imported ores, it follows that foreign materials accounted for 37 percent of Italy's lead consumption in 1936. Consumption of lead in 1935, which was exceptionally high, amounted to 72,628 tons—derived from a domestic production of 42,551 tons and net imports of 30,077 tons. Import duties are 170 lire a ton for lead ores and 450 lire a ton for pig lead.

Japan.—In 1936 Japan imported 95,900 metric tons of lead, an increase of 6 percent over 1935. Of the 1936 total, Canada was credited with 43,500 tons, British India with 13,000, the United States with 9,400, and other countries (probably mostly Mexico) with 30,000. The Anshan smelter, which began production in the latter part of 1935, is expected to supply a large part of Japan's lead requirements, although large-scale production apparently has not been achieved as yet.

Mexico.—Production of refined lead increased 20 percent in 1936. Operation of the smelter at San Luis Potosi was discontinued during the latter part of the year because of a strike which lasted 3 months. The decline in output at this plant, however, was offset by increased production at other plants. Refineries worked at 50 percent of capacity in 1936. Exports of lead amounted to 210,000 metric tons compared with 205,000 tons in 1935. Most of the lead exported from Mexico goes to Europe, but Japan has been a heavy buyer of Mexican lead in recent years. Exports of lead bullion to the United States for refining virtually ceased in 1936, but ore containing approximately 9,500 metric tons of lead was shipped to this country.

Newfoundland.—Production of lead concentrates in 1936 totaled 46,000 short tons compared with 48,100 tons in 1935. About 6,000 tons were exported to the United States in 1936, and the balance went to Europe.

Peru.—Early in 1937 the export tax on lead and zinc, which had been suspended for a considerable period, was reestablished. Cerro de Pasco is enlarging the capacity of its lead smelter at Oroya to 40,000 metric tons of refined lead per annum.

Spain.—The civil war disrupted the Spanish lead industry in 1936. Production has been estimated at 46,500 metric tons, a decline of about 35 percent from 1935. The annual output has declined steadily since 1929, and the 1936 output amounted to only one-third of the 1929 production.

U. S. S. R. (Russia).—Consumption has been estimated at 80,000 metric tons in 1936, of which approximately 30,000 tons were imported. Discovery of a large lead deposit in the Lake Balkhash region was reported in 1936.

United Kingdom.—Apparent consumption of pig lead exceeded all previous records in 1936 when 346,000 long tons were used. Production of pig lead declined, but imports increased from 316,000 tons in 1935 to 356,000 tons in 1936. Australia supplied 49 percent, Canada 25 percent, and India 14 percent of the 1936 imports. The British Metal Corporation, Ltd., estimates that 63 percent of the lead consumed in the United Kingdom is used in sheet, pipe, white lead, and oxide, 21 percent in cable, 6 percent in storage batteries, and 10 percent in miscellaneous products.

Mill Close Mines, Ltd., the largest producer in the United Kingdom, produced 10,000 tons less in 1936 owing to a fall in the grade of ore. Experiments are being conducted with a view to recovering by flotation the metal content of fines discharged from the mill. Attempts to revive lead mining in several of the old districts are being continued.

The Lead Industries Development Council, an organization of British lead producers, established a Technical Information Bureau in 1936, the object of which is to develop new uses and to improve old uses of lead. The Bureau will also endeavor to encourage standardization of lead products.

Yugoslavia.—Trepca Mines, Ltd., the largest producer of lead in Yugoslavia, treated 600,200 metric tons of ore, from which were obtained 65,700 tons of 80 percent lead concentrates containing nearly 27 ounces of silver per ton and 78,100 tons of 50-percent zinc concentrates. Exports of lead ore decreased from 74,900 metric tons in 1935 to 55,700 tons in 1936. Belgium continued to be the leading importer, taking over 35,000 tons, and Italy ranked second with 11,000 tons. Zletovo Mines, Ltd., with a reserve of nearly 1,000,000 tons of ore containing 11.5 percent lead, 3.5 ounces of silver per ton, and 1.7 percent zinc, is planning to erect a plant to treat 110,000 tons of ore annually for the recovery of lead and silver. Kapaonik Mines is to be brought into production in 1937. The ore will be treated at the Trepca mill.

Industrial use of slab zinc.....	199		

The zinc industry of the United States enjoyed its fourth consecutive year of recovery in 1936. Production, consumption, and price all increased decidedly over the 1935 figures, and stocks on hand at smelters at the close of the year were the lowest since 1928. In consequence of all these factors, zinc producers experienced their best year since 1929.

The St. Louis quotation for prime western zinc fluctuated between a low of 4.75 cents per pound established in July and a high of 5.45 cents at the close of the year. The average was 4.90 cents compared with 4.33 cents in 1935, but the increase was due more to the maintenance of levels attained during the latter part of 1935 than to the higher levels recorded during the last month and a half of 1936. From January to November quotations moved between the narrow limits of 4.75 and 4.90 cents. The statistical position during this period undoubtedly justified higher prices, but the unfavorable London market established a definite ceiling for domestic quotations. From January to November London prices were 2 cents per pound below the New York market. In view of the United States tariff of 1½ cents, this situation constantly threatened producers with the loss of domestic markets to foreign metal, imports of which increased to 11,660 tons, the highest amount recorded since the beginning of the century. This situation was relieved, however, by the tremendous buying wave in Europe, which began in the latter part of the year and continued into 1937. In March 1937 London prices actually exceeded domestic quotations.

¹ This report deals primarily with the smelting branch of the industry. Full details of zinc mining are given in the various State reports. Some zinc ore is used directly in the manufacture of zinc pigments. (See chapter on Lead and Zinc Pigments and Zinc Salts.)

Improvement in industry frequently is measured in terms of price, but it should be remembered that to a large extent price merely reflects the balance between production and consumption. Since there has been no dearth of zinc production in recent years, the increase in consumption has been the significant factor in the recovery experienced by this industry. In 1936 consumption of zinc of all kinds, except rolled zinc, increased substantially. Production of rolled products was satisfactory, and the slight decline in 1936 was due largely to a recession in the use of glass-jar tops, for which there was an unusual demand in 1935. Galvanizing, the principal use of zinc, increased 24 percent over 1935, and the use of zinc in brass was 35 percent greater, due in part to the record sales of brass pipe for water lines. Die castings took 30 percent more zinc in 1936 than in 1935 and the quantity used for this purpose in 1936 was twice

FIGURE 29.—Trends in the zinc industry in the United States, 1900-1936. Imports of slab and sheet zinc are not shown, as they seldom exceed 500 tons annually. In the last few years, however, they have increased, and in 1936 amounted to 11,900 tons.

that so used in 1929. Consumption of primary and secondary slab zinc was only 8 percent below the peak established in 1929.

Outside the United States production and consumption rose to higher levels although, as previously mentioned, the price situation was not satisfactory. During most of 1936 supplies exceeded demand, a situation that prompted British and Belgian producers to attempt reformation of the cartel. British participation was offered on the basis of preferential treatment for producers in the United Kingdom in their home markets. With Germany and Italy striving for self-sufficiency and France experimenting with higher tariffs, agreement on restriction of output was impossible. This forced producers in the United Kingdom to ask the Government for increased tariff protec-

tion. However, with the rapid rise in price and the shortage of supplies that developed during the latter part of the year, questions concerning cartel and tariff policies became relatively unimportant, and no action was taken up to the close of the year.

DOMESTIC PRODUCTION

Production of primary and secondary slab zinc.—Production of primary slab zinc from domestic and foreign ores in 1936 was 17 percent higher than in 1935 and was equivalent to 82 percent of the average output for the 5-year period 1925-29. It exceeded the depression low established in 1932 by 138 percent. Less than 0.1 percent of the total output in 1936 was derived from foreign ores. Production of secondary slab zinc increased 23 percent from 1935 and was 4 percent above the predepression 5-year average.

¹ All foreign zinc smelted in the United States was derived from Mexican ores.

² Includes 22 tons of secondary electrolytic zinc in 1930 and 312 tons in 1931.

Distilled and electrolytic zinc.—Of the total output of primary zinc in 1936, 74 percent was distilled and 26 percent electrolytic. Production of distilled primary zinc increased 21 percent in 1936, while that of electrolytic zinc increased only 7 percent. The latter was affected adversely by curtailment of operations in Montana the last half of the year owing to shortage of power. Production of redistilled secondary zinc increased 47 percent, the larger part of the increase being in the output at primary smelters.

Distilled and electrolytic zinc, primary and secondary, produced in the United States, 1929-36, in short tons

¹ For total production of secondary zinc see chapter on Secondary Metals.

² Includes 22 tons of secondary electrolytic zinc.

³ Includes 312 tons of secondary electrolytic zinc.

Production of primary slab zinc by States.—Pennsylvania, with an increase of 26 percent over 1935, continued to rank first in production in 1936, Montana ranked second despite a slight decrease in output, Illinois third, and Oklahoma fourth. All the production of Montana and Idaho is electrolytic zinc, whereas all the other States shown produce distilled zinc.

Secondary zinc.—Besides the redistilled and remelted secondary slab zinc (unalloyed) mentioned previously, a large quantity of secondary zinc is recovered each year in the form of alloys, zinc dust, zinc pigments, and zinc salts. Details are given in the chapter on Secondary Metals.

Byproduct sulphuric acid.—An important byproduct of zinc smelting is sulphuric acid made from the sulphur dioxide gases evolved from the roasting of zinc blende. Some of these plants also use large quantities of sulphur in addition to blende to utilize a larger proportion of their acid-producing capacity. The following table shows the production of sulphuric acid at zinc-blende roasting plants from 1929 to 1935. Data for 1936 were not available at the time this chapter was prepared.

Sulphuric acid (60° B. basis) made at zinc-blende roasting plants in the United States, 1929-35

¹ At average of sales of 60° acid.

² Includes acid made from small quantity of pyrites.

³ Includes acid from small quantity of foreign blende.

Rolled zinc.—Production of rolled zinc in 1936 decreased 3 percent from 1935. Some producers fabricate their rolled zinc into forms other than those shown in the accompanying table. In 1936, 11,077 tons of scrap resulting from zinc-rolling operations were remelted and rerolled. Zinc lost in waste products, such as skimmings and drosses and pot losses, totaled 1,690 tons in 1936—equivalent to about 3 percent of the net production of rolled zinc. Of the zinc purchased for rolling in 1936, 49 percent was brass special, 20 percent high grade, 16 percent selected, 12 percent prime western, and 3 percent electrolytic and intermediate grade. Stocks of slab zinc on hand at zinc-rolling mills were about 9,500 tons at the beginning and about 7,000 tons at the end of the year.

Rolled zinc produced and quantity available for consumption in the United States, 1935-36

¹ Figures represent net production. In addition, 13,551 tons of strip and ribbon zinc in 1935 and 11,077 tons of strip and ribbon zinc in 1936 were rerolled from scrap originating in fabricating plants operated in connection with zinc-rolling mills.

Zinc dust.—Commercial production of zinc dust in the United States was begun in 1910, and from 1922 to 1927 the annual production averaged about 8,000 tons. In 1936, 14,425 tons were produced, an increase of 16 percent over 1935 and the largest output ever recorded.

The zinc content of zinc dust produced in 1936 averaged 97 percent. Since 1931 virtually all zinc dust has been produced by redistillation of zinc drosses and slab zinc. The production of atomized zinc dust for market is relatively small.

Zinc dust ¹ produced in the United States, 1929-36

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average per pound			Total	Average per pound
1929.....	11,050	\$1,864,672	\$0.084	1933.....	11,157	\$1,308,594	\$0.059

1932.....	9,440	900,796	.048	1936.....	14,425	1,957,300	.068

¹ The zinc dust produced is principally "distilled." Some "atomized" dust was produced in each of the years shown except 1934-36, but the Bureau of Mines is not at liberty to publish the figures separately.

Zinc pigments and salts.—Zinc oxide, leaded zinc oxide, and lithopone are the principal pigments of zinc and chloride and sulphate the principal salts. These products are manufactured from various zinciferous materials—ores, metal, and secondary substances. Details of the production of zinc pigments and salts are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

Mine production.—Mine production of zinc increased 12 percent in 1936 and was equivalent to about 80 percent of the average pre-depression output. While all sections of the country shared in the advance, the Central States supplied more than half of the increase in tonnage. Oklahoma continued as the principal producer, although registering a decline in output. Kansas and Missouri more than made

up for this loss, so that the Tri-State district recorded a 19-percent rise for the year. In 1936 the district supplied 39 percent of the total production compared with 49 percent from 1925 to 1929. Resumption of operations at Metalline Falls accounted for the larger production in Washington.

STOCKS

Stocks of slab zinc on hand at primary and secondary smelters at the end of 1936 were the lowest since 1928. Stocks of the higher grades of zinc (A and B) declined from 13,546 tons at the beginning of the year to 7,536 tons at the close. Stocks of the lower grades (C, D, and E) were reduced from 78,144 tons to 48,590 tons. Less than 1 month's supply of zinc was on hand at the end of 1936.

Stocks of zinc on hand at zinc-reduction plants in the United States at end of year, 1929-36, in short tons

	1929	1930	1931	1932	1933	1934	1935	1936
At primary reduction plants.....	85,904	167,293	143,592	128,192	110,487	124,783	90,539	55,500
At secondary distilling plant.....	3,549	1,909	2,497	3,370	2,479	2,685	1,151	626
	89,453	169,202	146,089	131,562	112,966	127,468	91,690	56,126

Stocks of zinc ore in the Tri-State district also declined during 1936. On January 1 there was on hand about 17,000 tons of concentrates with an estimated recoverable zinc content of 9,000 tons, whereas on December 31 stocks of ore were less than 12,000 tons, representing about 6,000 tons of metal.

The only data available on stocks of slab zinc outside of the United States for 1936 are trade estimates. The British Metal Corporation, Ltd., in its review of nonferrous metals for 1935, stated that zinc stocks ex United States probably were less than 110,000 tons at the close of that year. For 1936, however, the corporation gives no estimate of totals but suggests that stocks may have declined about 10,000 tons. On this assumption foreign stocks of 100,000 tons at the end of 1936 are indicated, which, added to domestic holdings of 56,000 tons, makes a world total of 156,000 tons compared with 200,000 tons at the end of 1935.

DOMESTIC CONSUMPTION

New supply.—The supply of new zinc available for consumption in 1936 increased 18 percent over 1935 and equaled 98 percent of the 5-year predepression average. This remarkable recovery in zinc consumption exceeds that of copper, lead, and pig iron to a considerable extent, as consumption of new copper in 1936 was only 84 percent of the 1925-29 average, lead 55 percent, and pig iron 81 percent. The better showing of primary zinc may be ascribed to the fact that a smaller proportion of zinc than of copper and lead is consumed in the manufacture of capital goods, production of which has lagged behind consumers' goods. A large proportion of zinc is used in galvanized wares, paint pigments, radio and flashlight batteries, fruit-jar covers, and other items that pass on to the consuming public rapidly. Moreover, the uses to which zinc is put are such that there is much less return of scrap than for lead and copper.

Industrial use of slab zinc.—In addition to the new supply noted above, a large tonnage of secondary zinc is available each year for industrial use. The American Bureau of Metal Statistics estimates the total industrial use of primary and secondary zinc during the past 8 years as follows:

*Estimated industrial use of zinc in the United States, 1929-36, in short tons*¹

Purpose	1929	1930	1931	1932	1933	1934	1935	1936

	634,300	450,900	370,000	259,000	350,300	359,900	473,000	585,000

¹ Year Book, American Bureau of Metal Statistics, 1936.

² Includes pole-line hardware, hollow ware, chains, and all articles not elsewhere mentioned. The estimates for the use of slab zinc under this head, and also for wire cloth, are probably incomplete.

³ Includes all casting other than die casting, slush casting, and battery zinc.

⁴ Includes some duplication of tonnage.

⁵ Includes slab zinc used for manufacture of French oxide, lithopone, atomized zinc dust, wire, and zinc for wet batteries, slush castings, and desilverization of lead.

The industrial use of zinc in 1936 was the largest recorded since 1929. All important uses except rolled zinc took larger tonnages than in 1935, and the quantity used for die castings was twice that recorded in 1929. Galvanizing used 41 percent of the total zinc consumed in 1936 and took 24 percent more tonnage than in 1935. The totals for this item include 4,587 tons used in electrogalvanizing in 1936 and 3,115 tons in 1935, mostly in the manufacture of wire and wire cloth. Of the rolled zinc produced in 1936 (1935 figures in parentheses), 18,700 (15,300) tons were used for battery cans; 15,500 (18,000) for glass-jar tops; 1,200 (1,000) for boiler plate and special sheet not over 0.1 inch thick; 4,500 (4,800) for export; and the rest for miscellaneous purposes. Increased use of zinc in brass in 1936 reflects greater activity in automobile manufacture and building.

The sale of brass pipe for water lines is said to have exceeded all previous records. The principal use included in "other purposes" is French process zinc oxide, in the manufacture of which nearly 33,000 tons of slab zinc were used in 1936, compared to 27,000 tons in 1935. Other important miscellaneous uses include slush castings, cast zinc for wet batteries (2,174 tons in 1936), and lead desilverization. For the manufacture of brake lining 500 tons of zinc wire was used in 1936 and 300 tons in 1935.

PRICES

The price of zinc increased further in 1936. The average for prime western at St. Louis was 13 percent above the 1935 price but was still 28 percent below the 1925-29 average. Zinc, however, has fared better than copper and lead as to price advances, as 1936 averages for those two metals were, respectively, 35 and 37 percent below pre-depression levels.

At the beginning of the year the quotation stood at 4.85 cents. There was little change during the first half of the year, but from the latter part of June to the middle of July there was a temporary sag from 4.90 to 4.75 cents, the latter proving to be the low for the year. During the last 2 months buying became brisk, and the quotation rose from 4.85 cents early in November to 54.5 cents at the close of the year.

Domestic price movements were restricted by the London market, which was held back most of the year by an abundance of supplies. For the first 10 months of 1936 the differential between London and New York prices averaged about 2 cents. Since this was higher than the United States import duty of 1½ cents, domestic producers could not raise prices farther without losing business to foreign producers. The upward swing in prices resulting from the buying spree that began the latter part of the year was more pronounced in Europe than in the United States. London prices therefore moved forward more rapidly, and by December the differential between London and New York had declined to 1.72 cents. In March 1937, London prices actually exceeded domestic quotations.

The price of 60-percent zinc concentrates at Joplin was 11 percent higher than in 1935. The smelter margin was 2.24 cents per pound of zinc compared with 1.93 cents in 1935 and 2.96 in 1929.

ZINC-REDUCTION PLANTS

Zinc smelters.—At the close of 1936 there were 21 primary zinc-distillation plants in the United States, of which 17 were active sometime during the year and 4 were idle throughout the year. The Illinois Zinc Co. shut down its smelter at Peru, Ill., and started up its new plant at Dumas, Tex. The new plant has two natural-gas-fired horizontal-retort blocks and is reported to have the capacity to produce 12,000 tons of metal annually. Dismantling the plant at Kusa, Okla., which had been idle since 1932, was completed in 1936. The St. Joseph Lead Co. began large-scale production of metallic zinc at its electrothermic smelter near Josephstown, Pa. Formerly this plant had been producing only zinc oxide. Early in 1937 the Van Buren, Ark., smelter, which shut down in 1927, was acquired by interests associated with the Eagle Picher Mining & Smelting Co. According to reports, the plant will be rehabilitated and put into operation soon. Additional vertical-retort furnaces were installed at Palmerton during 1936.

At 16 plants active during 1936 there was a total of 66,972 horizontal retorts available for use, of which 40,903 were in operation at the close

of the year. At 3 of these plants there were 52 continuous vertical-retort furnaces, all of which were in production at the close of the year.

Many of the primary smelters treat scrap as well as ore. Horizontal-retort plants at Beckemeyer and Sandoval, Ill., and large graphite retort plants at Trenton, N. J., Philadelphia and Bristol, Pa., Wheeling, W. Va., and Tottenville, N. Y., operate exclusively on scrap.

Electrolytic plants.—The Evans-Wallower Zinc Co. plant at East St. Louis has been idle since 1931. The Anaconda plant of the Anaconda Copper Mining Co. resumed operations early in 1936 and the Great Falls plant was active all year, but operations at both plants were curtailed during the last half of the year owing to shortage of power as a result of the drought. The Kellogg plant of the Sullivan Mining Co. maintained full-scale production during 1936, and a substantial increase in capacity is being planned. At the 3 active plants, 1,464 cells out of a total of 2,040 were in use at the end of the year.

TECHNOLOGY

Mining.—Mechanical loading has been an important factor in reducing the cost of mining and in making possible operations in mines where high temperatures preclude efficient hand shoveling. A survey² conducted by the Bureau of Mines shows that from 1923 to 1936, 3,752 scraper loaders and 470 shovel loaders were added to the mechanical equipment of underground metal and nonmetallic mines in the United States. It also shows that interest in mechanical loading is widespread and that the potential use of such equipment is large. Adoption of mechanical loading in the Tri-State district has been retarded by the small scale of the operations under which capital investment for mechanical equipment would not be justified. Several zinc mines in the Eastern, Southern, and Western States are equipped with mechanical loaders.

Detachable drill bits appear to be gaining favor, although opinions on their merits vary greatly. The Bureau of Mines has issued two reports on the subject, Information Circulars 6877 and 6911. At plants not equipped with elaborate drill-sharpening equipment for old-style drill steel, hot milling is preferred to forging methods. The practice in the Wisconsin zinc fields is described in Bureau of Mines Information Circular 6907.

At the Sullivan mine, British Columbia, the problem of mining pillars has necessitated the filling of rather flat-dipping open stopes. This is being accomplished by discharging a free-flowing mud into the stopes through openings at the surface. Excess water is drained from the mud through outlets provided in a concrete dam constructed at the bottom of the stope. On the surface, clay and gravel are conveyed, by means of bulldozers of the caterpillar type, to a grizzly covering the raise from the stope. The water is added just below the grizzly and mixes with the dry dirt as the mass descends. It is expected that the mixture will set sufficiently to permit easy pillar recovery.

Milling.—R. A. Pallanch³ aptly calls attention to the fact that metallurgical practice is governed to a large extent by economic considerations and that the efficiency of separation processes must be

² Plein, L. N., Berquist, F. E., and Tryon, F. G., *Mechanical Loading Underground*: Eng. and Min. Jour., vol. 138, no. 5, 1937, p. 241.

³ Pallanch, R. A., *Factors Governing the Separation of Lead and Zinc in Ore by Flotation*: Min. and Met., vol. 17, no. 356, 1936, pp. 386-389.

gaged in terms of "economic recovery." He also points out that while selective flotation has been a boon to the lead-zinc millman, it has its limitations. These can be determined by use of the microscope, thus eliminating much useless effort in trying to achieve impossible results.

In the Tri-State district, the Eagle-Picher Mining & Smelting Co. has announced its intention to increase the capacity of the central mill from 6,000 to 10,000 tons per day. This company apparently is looking forward to an increased supply of ore from the older sections of the district in the vicinity of Joplin. In this connection, the use of screens and picking belts by the Webb City Lead & Zinc Co. to improve the grade of ore in the Webb City-Oronogo field from 4.5 percent zinc to 7 and 8 percent is of interest. The higher-grade product can be shipped profitably to Eagle-Picher's Central mill.

A new edition of *Flotation Plant Practice* by P. Rabone was published in 1936.

Reduction.—No branch of metallurgy has shown more improvement in the last decade than that of zinc. Refinements in the electrolytic process and the introduction of large, vertical, continuously operated retorts have threatened extinction of the small horizontal-retort process, which had been standard practice for over a century. However, the erection in 1936 of a new plant using horizontal-retort smelting indicates that under some conditions, this process is still desirable. The new plant is that of the Illinois Zinc Co., at Dumas, Tex. It contains two gas-fired retort blocks with a capacity of 12,000 tons of metal per year, and further increase in capacity is anticipated. The plant uses natural gas as fuel and smelts zinc ores from the company mine in New Mexico.

The Queneau process offers possibilities for the production of higher grades of zinc by retort smelting and improved recovery of byproducts such as cadmium. The calcined concentrate is subjected to a chloridizing roast, which removes most of the contaminating metals and leaves an exceptionally pure product for zinc distillation. A similar process, in which fluorides are used instead of chlorides, also has been proposed.

Bunce⁴ has described the vertical-retort, continuous-smelting process developed by the New Jersey Zinc Co. Twelve new furnaces were installed at Palmerton during 1936, making the total 28 at this plant. This type of furnace is used also at Depue, Ill.; Meadowbrook, W. Va.; Avonmouth, England; and Oker, Harz, Germany.

According to U. C. Tainton,⁵ major improvements in the electrolytic process cannot be visualized except by a complete change in the method of attack. The modern plant makes metal 99.99 percent pure with 99.999 percent metal in the offing. Recovery ranges from 95 to 99 percent of the zinc contained in the feed. Conversion of high-tension alternating to direct current is accomplished with an efficiency of about 95 percent, and current efficiencies are 90 percent or better. Large-scale production has cut labor costs to very little. The Sullivan plant at Kellogg, Idaho, is being enlarged, and several new plants are under construction abroad. During 1936 a second plant for zinc-coating steel wire by electrolysis was put into operation at Johnstown, Pa. The plant uses roasted zinc ore as a raw material.

⁴ Bunce, E. H., *An Advance in Zinc Smelting*: Eng. and Min. Jour., vol. 137, no. 11, December 1936, pp. 599-607.

⁵ Tainton, U. C., *Metallurgy of Zinc*: Min. and Met., vol. 18, no. 361, January 1937, p. 17.

Commercial production of metallic zinc by electrothermic smelting was begun in 1936 at the Josephtown, Pa., plant of the St. Joseph Lead Co. The smelter was erected in 1930, but heretofore it has produced only zinc oxide. Sulphuric acid is produced as a byproduct. The process was described by George F. Weaton at the February 1937 meeting of the American Institute of Mining and Metallurgical Engineers. Weaton's paper, as well as many others describing the present state of zinc metallurgy, is included in volume 121, Transactions of the Institute, entitled "Metallurgy of Lead and Zinc", published in 1937.

FOREIGN TRADE ⁶

Imports.—The following tables give zinc imports into the United States from 1930–36, inclusive, and a record of bonded-warehouse inventories.

Zinc ores imported into the United States, 1930–36, in short tons ¹

Year	Canada	Mexico	Other countries	Total	Year	Canada	Mexico	Other countries	Total
1930.....	13	25,644	182	25,839	1934.....	(²)	14,277	(²)	14,277
1931.....	(²)	778	2	780	1935.....		10,520		10,520

1936.....	¹ 10,690,832	(²)	(²)	(²)	(²)	(²)

¹ "Blocks, pigs, and old" included with "ore"; not separately recorded.

² Data not available.

Imports of zinc ore virtually ceased in 1936 and were the lowest recorded in over 30 years, but imports of slab zinc more than doubled and were the highest since the beginning of the century. Of the 11,660 tons received in 1936, 6,869 came from Mexico, 2,301 from Norway, 1,204 from Canada, 1,058 from Poland, and 228 from other countries. Much of the metal imported is used in manufactures and exported with benefit of draw-back.

⁶ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Zinc imported for consumption in the United States, 1930-36

¹ Includes 33 tons of dross and skimmings, valued at \$1,829, imported June 18 to Dec. 31; not separately recorded prior to change in tariff.

² Less than 1 ton.

³ Includes 29 tons of dross and skimmings valued at \$974.

⁴ Includes 14 tons of dross and skimmings valued at \$721.

Exports.—The total value of the 1936 exports of zinc ore and domestic and foreign manufactures of zinc (not including galvanized products, alloys, and pigments) was approximately \$1,008,000, a decrease of 7 percent from 1935 and 94 percent from the recent high in 1925. Exports of sheet and strip zinc declined 7 percent in 1936. Besides the items shown in the accompanying tables, considerable zinc is exported each year in the form of brass and pigments and in galvanized iron and steel. The American Bureau of Metal Statistics estimates that 10,900 tons of zinc were exported in galvanized products in 1936 compared with 12,800 tons in 1935. Export data on zinc pigments and chemicals are given in the chapter on lead and zinc pigments and zinc salts. Much of the zinc used in the manufacture of these products is of foreign origin and when exported a draw-back is paid amounting to 99 percent of the import duty. In 1936, draw-back was paid on 8,909 tons of zinc, of which 5,009 tons had been imported as slabs and 3,900 tons as ore. Totals for previous years were: 1935, 7,297 tons; 1934, 4,139 tons; and 1933, 857 tons.

WORLD ASPECTS OF THE ZINC INDUSTRY

International (European) Zinc Cartel.—Efforts to revive the Zinc Cartel, which had collapsed in December 1934, were continued throughout 1936 but without success. Producers in Belgium and the United Kingdom led in negotiations for an agreement to control excess supplies, which were having an adverse effect on prices. British producers urged the adoption of such an agreement in lieu of an increase in the tariff on zinc, which, as revised in 1935, they said, had proved to be inadequate. In July a general 10-percent cut in production was proposed, but German, Italian, and French interests were apathetic. It was also rumored at one time that a proposal had been made to pool part of the concentrate production for 1 year. Toward the latter part of the year, as the market improved, interest in revival of the cartel dwindled.

World production.—World production of zinc (smelter basis) increased 10 percent in 1936 and was the highest on record, exceeding the previous peak established in 1929 by about 2 percent. Compared with 1935 the United States showed greater improvement than the rest of the world, the respective increases being 17 and 7 percent. Compared with 1929, however, the production of foreign countries increased 16 percent, whereas that of the United States decreased 21 percent. From 1929 to 1936 the United States proportion of the world total declined from 39 to 30 percent.

World smelter production of zinc, 1929-36, in metric tons, by countries where smelted

¹ Exclusive of secondary material (Metallgesellschaft). The figures published by the Stat. Reichsamt, which include secondary material, are as follows: 1929, 108,429 tons; 1930, 101,385 tons; 1931, 48,621 tons; 1932, 45,035 tons. Similar data not available for 1933-36.

² Approximate production.

³ Data not available. Estimate included in total.

⁴ Year ended Sept. 30.

⁵ Some secondary material included.

World consumption.—World consumption of zinc in 1936 exceeded all previous records. According to the American Bureau of Metal Statistics it amounted to 1,529,100 metric tons, which was 13 percent above that of 1935 and 4 percent over the previous peak consumption in 1929. There was a greater increase in the use of zinc in the United States in 1936, as compared with 1935, than in the rest of the world, domestic consumption having increased 22 percent, whereas elsewhere it increased only 9 percent. Compared with 1929, however, the United States lags behind. The quantity of zinc consumed in 1936 in foreign countries was 9 percent more than that of 1929, but in the United States it was 4 percent below.

The United States continued to be the largest consumer, having taken about 34 percent of the total. Next in order in percentage of total consumed were United Kingdom 14 percent, Germany 14 percent, Belgium 7 percent, France 6 percent, Japan 5 percent, U. S. S. R. (Russia) 4 percent, and Poland and Italy each 2 percent. France was the only important consumer to take less in 1936. Consumption in other nations increased as follows: United Kingdom 10 percent, Germany 5 percent, Belgium 10 percent, Japan 22 percent, U. S. S. R. (Russia) 39 percent, Poland 19 percent, and Italy about 1 percent.

REVIEW BY COUNTRIES

Australia.—Australia's increase in production of metal in 1936 was the result of the first full year's operation of the new unit of the Risdon electrolytic zinc plant. At Broken Hill production of ore increased to 1,350,300 long tons, an advance of 42,700 tons over 1935. Zinc-concentrate production increased from 220,767 to 243,604 tons. Production of zinc concentrates was begun at Mount Isa in 1936, and

the output for the year contained over 30,000 tons of zinc. Exports were begun in March but were suspended in September. The company stated that freight rates were exorbitant, amounting to 40 percent of the sales value of the concentrates. In February 1937 it was stated that 35,000 tons of concentrates were stocked and awaiting shipment. The Rosebery mine in Tasmania resumed production in February, and early in 1937 it was reported that a 1,000-ton mill was to be erected to treat ore from the Lake George mine, New South Wales. Exports of slab zinc and concentrates from Australia increased in 1936.

Belgium.—Imports of zinc ore amounted to 576,000 metric tons in 1936, an increase of 37 percent over 1935. Larger shipments were obtained from Mexico, Peru, Newfoundland and Canada, and Australia, but receipts from Yugoslavia and British India declined. Exports of zinc slabs and zinc sheets were 92,000 tons and 45,500 tons, respectively, representing a decline from 1935. It was reported that Vieille Montagne and Société Anonyme Metallurgique de Prayon had taken over control of Société Anonyme La Nouvelle Montagne. The new 6,000-ton electrolytic zinc plant of Vieille Montagne operated throughout the year. Export business is an important factor in the Belgian zinc-smelting industry, and the increasing number of import restrictions being adopted throughout the world constitute a serious threat to Belgium's producers. In 1936 it was suggested that further limitation of available world markets would force Belgium to extend its activity in the fabrication of zinc products.

Canada.—Eighty percent of Canada's production of metallic zinc was made at Trail and 20 percent at Flin Flon. Production at Trail increased 5 percent and that at Flin Flon 7 percent. Exports of slab zinc increased 3 percent, to 140,000 short tons, of which the United Kingdom took 81 percent and Japan 12 percent. Exports of zinc in the form of ore increased from 9,800 to 19,566 tons, Belgium taking 81 percent of the latter. Increase in exports of ore resulted from resumption of operations at the Stirling mine in Nova Scotia. The Britannia mine in British Columbia and the Tetreault mine in Quebec also exported more zinc concentrates in 1936. Sherritt-Gordon is considering reopening its mine in Manitoba during 1937, and preliminary steps have been taken to reopen the Waite Amulet mine in Quebec.

Czechoslovakia.—Zinc producers applied to the Government for an increase in import duties to permit them to engage in the production of electrolytic zinc, hitherto imported. Consumers protested on the ground that such action would be uneconomic. Apparently no action was taken.

France.—French subsidies to domestic and colonial producers did not succeed in increasing materially the mine output. Higher zinc prices toward the end of the year, together with devaluation of the franc in September, improved the situation somewhat, and at the close of the year reopening of some of the mines was being considered. Smelter output increased 4 percent, necessitating an increase in imports of zinc concentrates. During 1936, 196,000 metric tons were imported. Imports of slab zinc declined from 37,000 to 31,800 tons.

Germany.—Despite heroic efforts to make Germany self-sufficient with respect to zinc supplies, there was no appreciable change in amount of net imports, which approximated 120,000 metric tons in 1935 and 1936. Smelter production rose 10 percent and contributed

a slightly higher percentage of the total consumption of 209,000 tons. The slight decline in imports of metal thus permitted was offset by larger imports of ore. Government subsidies have stimulated zinc mining, but the mine output in 1936 apparently was 50,000 tons short of smelter requirements.

The Magdeburg electrolytic zinc plant operated at capacity during 1936, and an increase in capacity from 40,000 to 60,000 tons per annum is under way. The new retort smelter at Oker (40,000 tons annual capacity) opened in the latter part of the year, and full-scale operation is expected before the end of 1937. Zinc is being substituted wherever possible for other metals for which Germany depends largely on imports.

India, British.—The Burma Corporation, Ltd., produced 76,807 long tons of zinc concentrates averaging nearly 58 percent zinc in 1936 compared with 78,590 tons of 57 percent grade in 1935. The concentrates were shipped largely to Europe. Imports of slab zinc, used largely in the manufacture of galvanized products, declined from 22,756 to 21,272 tons.

Italy.—Statistical details of the Italian industry for 1936 are not available, because publication of all official statistics was suspended in the middle of the year. Exports of zinc ore apparently increased, as Germany reported receipts of 17,000 metric tons in 1936 compared with only 2,000 tons in 1935, while Belgian receipts were unchanged at 17,000 tons. According to some reports, the Porto Marghera electrolytic zinc plant, when completed in 1937, will have capacity to produce 12,000 tons per year instead of the 6,000 originally planned.

Japan.—Apparent consumption of zinc in Japan in 1936 was 78,200 metric tons compared with 67,000 tons in 1935. Of the 1936 total, 54 percent was supplied by imported metal and approximately 31 percent by imported ores. Domestic mines, therefore, furnished only 15 percent of Japan's needs. Imports of metal totaled 42,000 tons, Canada, Australia, and the United States being the principal sources.

Mexico.—Mine production of zinc in 1936 totaled 150,250 metric tons compared with 135,921 tons in 1935. Smelter production is estimated at 40,000 tons, leaving approximately 110,000 tons available for export in the form of ore. Belgium reported receipts of 153,000 tons of Mexican ore in 1936, France 29,000 tons, Germany 21,000 tons, United Kingdom 2,500 tons, and the United States less than 200 tons.

Newfoundland.—Production of zinc concentrates decreased from 146,000 short tons in 1935 to 141,000 in 1936. In addition, over 46,000 tons of lead concentrates were produced in 1936. All of the zinc concentrates and the greater part of the lead concentrates are shipped to Europe for smelting.

Poland.—The increase in smelter output in 1936 was partly derived from larger imports of ore. Germany, formerly the principal foreign source of zinc ore smelted in Poland, supplied less than 8,000 metric tons of a total of 73,000 purchased abroad in 1936. The remainder was obtained from Rumania, Greece, and Italy. Exports of slab zinc amounted to 61,600 tons, of which Germany took about 27,000 tons. Giesche Spolka Akcyjna produced about 43,000 tons of zinc in 1936.

Spain.—Civil war in Spain evidently has not affected operations at the Reocin mine in northern Spain, as French imports from Spain were considerably higher in 1936 than in 1935. The Reocin ore goes to France for roasting and is then forwarded to Norway for con-

version into electrolytic zinc. The Norwegian plant operated at capacity throughout 1936. Zinc mining in southern Spain probably has declined considerably.

U. S. S. R. (Russia).—Zinc production increased further in 1936. Plans for a new smelter near Gloubokoie in the Altai district are reported to have been ratified, and at Kirovgrad in the Urals a plant is under construction that will treat annually 250,000 to 300,000 tons of copper slag containing 5 to 6 percent zinc. The U. S. S. R. is now virtually self-sustaining with regard to zinc.

United Kingdom.—The smelter output of zinc increased 3 percent in 1936. The industry is supported largely on foreign ores, imports of which decreased from 152,000 long tons in 1935 to 130,000 in 1936. The decline was mainly in shipments from Australia. As the local smelting industry is inadequate for the needs of the country, large imports of metal are required. Net imports were 174,000 tons in 1936 and 151,000 in 1935. Consumption increased 10 percent over 1935 and totaled 217,000 tons.

The Imperial Smelting Corporation, Ltd., the only zinc-smelting company in the United Kingdom, operated its new vertical-retort plant at Avonmouth at capacity throughout the year. In November the company announced that owing to losses sustained the Seaton Carew smelter had been shut down and that it also purposed closing the Bloxwich plant, which operates largely on scrap. The company was active during 1936 in promoting a renewal of the cartel but insisted that it should be given preferential treatment in the British market. Following the collapse of cartel negotiations in the latter part of the year, the company asked the Government for an increase in the import duty on zinc. Such action, however, would have been difficult in view of the Ottawa agreement. Under a recent trade treaty negotiated with Canada, the British Government is free to impose a tariff on Canadian zinc, on which British consumers depend to a great extent. With the rising market at the close of 1936 and early in 1937, immediate action in this respect seemed improbable. Early in 1937 it was rumored that the Government was acquiring large quantities of zinc.

Yugoslavia.—Trepca Mines, Ltd., treated 600,200 metric tons of ore in 1936, from which 78,100 tons of 50-percent zinc concentrates and 65,700 tons of 80-percent lead concentrates were obtained. The ore averaged about 7 percent zinc, 9 percent lead, and 3.2 ounces of silver per ton. The declining zinc content of the ore in the lower levels of the mine accounts for a 15-percent decline in the production of zinc concentrates. The zinc concentrates are shipped to Belgium and France for smelting. The operations of this company were described in detail in the September to December 1936 issues of *Mining and Metallurgy*.

LEAD AND ZINC PIGMENTS AND ZINC SALTS

In consequence of the greater demand for paint, automobiles, pneumatic tires, and storage batteries—all major pigment-consuming industries—sales of lead and zinc pigments in 1936 increased 14 percent over 1935 in both value and tonnage. Compared with 1925–29 averages, however, sales were still 39 percent lower in value but only 12 percent lower in tonnage, indicating that prices have not improved to the same extent as production.

Salient statistics of the lead and zinc pigments industry of the United States, 1925–29 (average) and 1932–36

	1925-29 (average)	1932	1933	1934	1935	1936

¹ Import balance.

Lead pigments again fared better than zinc pigments. Total sales of lead pigments increased 22 percent in value and 16 percent in quantity whereas zinc pigments increased only 5 percent in total value and 13 percent in quantity. Producers of lead pigments received nearly \$7 per ton more for their product in 1936 than in 1935, while zinc pigments brought \$6 less per ton. Trends in lead pigment quotations during 1936 paralleled those of metallic lead, but prices of zinc pigments did not respond to the sharp increase in the zinc quotation. Prices of the zinc oxides, for instance, were increased only 0.25 cent per

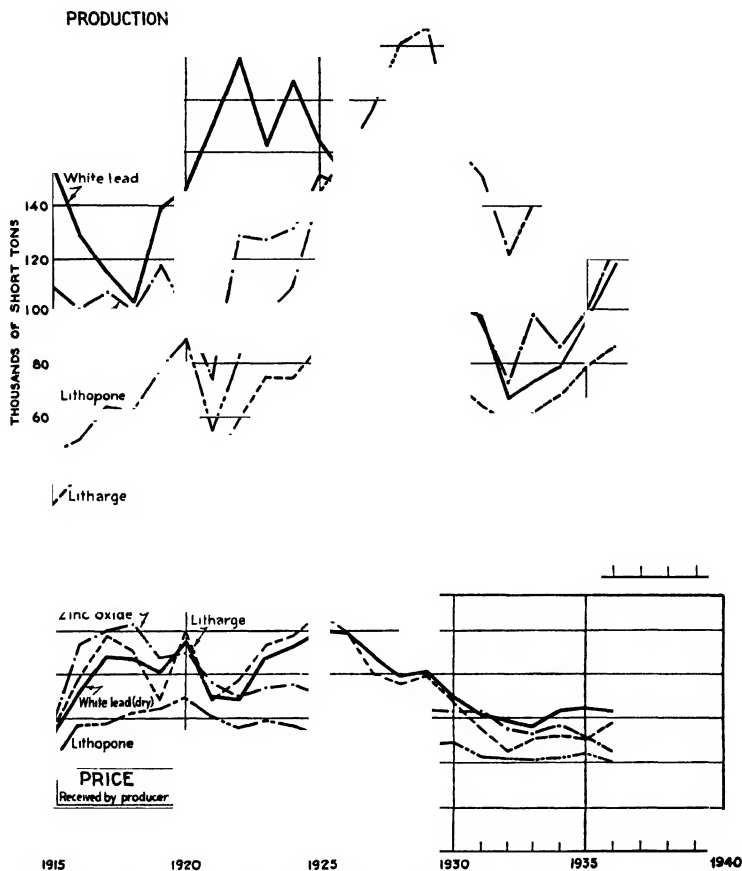

FIGURE 30.—Production and price trends of the principal lead and zinc pigments, 1915-36.

pound during 1936 whereas the price of metal rose 0.60 cent between January 1 and December 31. The lower sales realization on zinc pigments in 1936 resulted from the drastic cut in prices put into effect the latter part of 1935 and the 0.25-cent reduction in lithopone prices in November 1936. The latter was prompted by a 1-cent cut in the quotation for titanium dioxide.

Comparison of the sales of the white-lead pigments and zinc oxides to the paint trade in recent years reveals substantial gains in the use of leaded zinc oxide. In 1932, total sales amounted to 105,529 short tons, of which white and sublimed lead comprised 66 percent, zinc

oxide 21 percent, and leaded zinc oxide only 13 percent. By 1936 total sales had increased to 194,762 tons, of which the lead pigments supplied 62 percent, zinc oxide 17 percent, and leaded zinc oxide 21 percent. For the same period the average lead content of the latter pigment increased from 23 to 27 percent and production nearly trebled.

Tyler¹ has pointed out the rapid increase in production of titanium pigments and their expanding use in fields formerly supplied exclusively by lead and zinc pigments. Much of this expansion has taken place during a period when prices of lead and zinc were extremely low. Even under these conditions titanium enjoyed a distinct advantage from the standpoint of low-cost raw materials, as ilmenite, the principal source of titanium, was considerably cheaper than lead and zinc ores. Recent sharp rises in lead and zinc prices, coupled with the fact that there has been no appreciable change in the cost of ilmenite, has favored the competitive position of titanium. In this connection the drop in the price of lithopone in 1936 in the face of a rising metal market was significant. Further increase in imports of ilmenite in 1936 suggests a record production of titanium pigments in that year.

PRODUCTION

In this report, sales of pigments and salts are considered to represent production, as no account is taken of the stocks on hand at the beginning and end of the year. The quantities used by producers at their own plants are included under sales.

The total value of lead and zinc pigments sold by domestic producers was approximately \$62,068,000 in 1936 compared with \$54,564,000 in 1935. The total value of all lead pigments sold was \$34,206,000 and that of all zinc pigments sold \$27,862,000. Sales of lead pigments increased 22 percent in total value and 16 percent in quantity, whereas sales of zinc pigments increased 5 percent in total value and 13 percent in quantity. The average value per ton of lead pigments sold in 1936, as reported by producers, increased only 5 percent, whereas the average New York quotation for pig lead increased 16 percent. Zinc pigments decreased 7 percent in value per ton compared with a 13-percent increase in the St. Louis quotation for slab zinc.

Lead pigments.—Production of all lead pigments except orange mineral, which declined only slightly, increased in 1936. Production of white lead increased 22 percent but was 39 percent below the peak of 1922. Production of litharge was 8 percent higher than in 1935 and nearly equaled the record output of 1929; and the output of red lead, which increased 21 percent in 1936, was 19 percent below that of 1929. Production of sublimed lead was 1 percent more than in 1935. Unit values of all lead pigments except white lead in oil increased in 1936.

Zinc pigments and salts.—Production of zinc oxide and leaded zinc oxide increased 27 and 35 percent, respectively, in 1936, the output of the latter being the highest on record. The tonnage for lithopone represents a decline of 1 percent from 1935, due to a change in the method of compiling statistics. Formerly the combined weights of standard-grade and high-strength lithopone were reported as total sales. Beginning with 1936 the total will include sales of standard grade plus the standard-grade content of the high-strength product. This change reduces the tonnage by the excess quantity of zinc sulphide contained in high-strength lithopone. Production in 1936, compiled on a basis comparable to former years, would show a moderate increase in output over 1935. The Bureau of Mines is not at liberty to publish statistics on the new basis for past years.

The 1936 tonnages were equivalent to the following percentages of the 1929 outputs: Zinc oxide, 79; leaded zinc oxide, 149; and lithopone, 77. Unit values of the oxides decreased substantially in 1936, and that of lithopone was slightly lower.

¹ Figures not available**CONSUMPTION BY INDUSTRIES**

White lead.—About 95 percent of the white lead produced is used in the manufacture of paint. The tonnage used in this industry in 1936 was 24 percent above that in 1935, but 17 percent below that in 1929. Consumption of white lead in the ceramic industry increased 45 percent in 1936.

Distribution of white lead (dry and in oil) sales, 1929-36, by industries, in short tons

Basic lead sulphate.—This pigment is used largely in paint, and the quantity so used in 1936 was 5 percent above that in 1935 but 40 percent below that in 1929. In 1929 over 2,000 tons of basic lead sulphate were used in storage batteries, but this use has since dwindled. Large quantities of this pigment are used in leaded zinc oxide to increase the lead content. In 1936, approximately 2,400 tons were

used for this purpose by pigment producers reporting to the Bureau of Mines. This tonnage is not included in the accompanying statement of sales of basic lead sulphate but is included in figures shown for leaded zinc oxide. It is the Bureau's policy to measure production of a plant in terms of final products.

Distribution of basic lead sulphate sales, 1929-36, by industries, in short tons

Litharge.—The principal use of litharge is in the manufacture of storage batteries, but this outlet has been affected adversely by the growing tendency of battery makers to substitute a black oxide or suboxide of lead, which they manufacture themselves. This practice was begun in 1923, and by 1929 a total of 33,000 tons of the black oxide was being made. In 1936 one battery maker began the manufacture of litharge. In all, 40,832 tons of oxides were made at battery plants in 1936 compared with 34,146 tons in 1935. None of this is included in the Bureau of Mines statement of litharge production.

¹ Included under "Other." Not separately reported.

Red lead.—The use of red lead in storage batteries and paints in 1936 increased 15 and 35 percent, respectively, over 1935. The quantity used in paints nearly equalled the amount used in 1929.

Distribution of red lead sales, 1929-36, by industries, in short tons

Zinc oxide.—Total sales of zinc oxide were 27 percent higher in 1936 than in 1935. All uses shared in the increase except floor coverings and textiles, which remained virtually unchanged from 1935. In the preparation of exterior paints, manufacturers are using smaller proportions of zinc oxide than formerly. Of the 1936 total, 42 percent was made by the French process and 58 percent by the American process, the same ratios as in 1935. The proportion of French-process oxide made from scrap zinc was virtually the same in 1936 as in 1935. Over 3,000 tons of zinc oxide, not included in the sales figures given herein, were used to make leaded zinc oxide in 1936. This tonnage is included under leaded zinc oxide.

Leaded zinc oxide.—This pigment is used almost entirely in the manufacture of paint. The quantity sold for that purpose in 1936 was 36 percent more than in 1935. The present trend toward higher lead content in exterior paints is reflected in the large increase in use of leaded zinc oxide in 1935 and 1936. Some manufacturers now are marketing a 50-percent leaded zinc oxide. The tonnage stated under this heading includes approximately 2,400 tons of basic lead sulphate and over 3,000 tons of zinc oxide used by producers in the manufacture of leaded zinc oxide.

Distribution of leaded zinc oxide sales, 1931-36, by industries, in short tons

Industry	1931	1932	1933	1934	1935	1936
Paints.....	18, 292	14, 072	22, 488	20, 376	29, 632	40, 156
Rubber.....	38	26	46	28	36	32
Other.....	247	207	334	102	308	324
	18, 577	14, 305	22, 868	20, 506	29, 976	40, 512

Lithopone.—Sales of lithopone to the paint industry, as shown in the accompanying table, decreased slightly in 1936, but figures for the latter years are not comparable to those for previous years for reasons previously mentioned. Comparable figures would probably show a moderate increase in the use of regular and high-strength lithopone in

paint in 1936. The production of floor coverings and textiles rose appreciably in 1936. Of the total for that year approximately 6,800 tons were used in coated fabrics and textiles and the balance in linoleum and felt-base floor coverings. This distribution includes an estimate for one producer who was unable to segregate sales under these headings. Other items obtained in 1936 for which 1935 data are not available include paper, 1,629 tons, and ink, 321 tons. Lithopone production capacity was reported at 230,320 tons per year in both 1935 and 1936.

Lithopone is used extensively in interior paints, and in this field is now subject to intense competition from titanium pigments.

Distribution of lithopone sales, 1929-36, by industries, in short tons

Industry	1929	1930	1931	1932	1933	1934	1935	1936
Paints, etc.....	150, 804	126, 076	119, 446	93, 465	106, 995	114, 472	124, 615	122, 461

Other.....	10, 829	8, 336	5, 791	6, 646	10, 286	11, 696	10, 996	7, 865
	206, 315	164, 065	151, 850	121, 667	140, 831	145, 565	159, 486	158, 319

Zinc sulphide.—Production of this pigment was reported by five plants in 1936; but owing to the fact that one producer represents such a large part of the total, the Bureau of Mines is unable to publish statistics. Most of the zinc sulphide is mixed with regular lithopone to make high-strength lithopone.

Zinc chloride.—The Bureau of Mines cannot report zinc chloride production because of the refusal of one of the large producers to supply reliable data.

According to the Department of Agriculture, the consumption of zinc chloride by wood-treating plants totaled 2,050 tons in 1936. From a peak of 26,000 tons (solid basis) in 1921, consumption of zinc chloride in this field declined to 1,600 tons in 1934. The loss of this market is due primarily to the fact that zinc chloride is soluble in water and therefore is not as effective as creosote, its principal competitor, in preserving wood exposed to moisture. From time to time various insoluble zinc preservatives have been developed, but none has found a wide market. Recently a chromated zinc was introduced, but enough time has not elapsed to gage its effect on this market for zinc.

Complete data on sales of zinc chloride in 1936 are not available, but returns received from producers representing roughly two-thirds of the total output indicate the following distribution of sales by uses in 1936:

	Percent		Percent
Soldering flux.....	24	Oil refining.....	5
Wood preserving.....	23	Others.....	10
Dry-cell batteries.....	25		
Vulcanized fiber.....	13		100

Zinc sulphate.—In 1935 and 1936 producers of zinc sulphate were asked to distribute their sales according to various industries. The results of the canvass are not very satisfactory because the distribution was incomplete. Producers selling large tonnages to jobbers were unable to classify sales of this type by consuming industries.

Of the total 1936 sales (8,687 tons), 4,201 tons were reported as sold to the rayon industry, 331 tons to electro-galvanizers, 339 tons to glue manufacturers, 124 tons to printers and dyers of textiles, and 113 tons to paint and varnish manufacturers; 3,579 tons were undistributed. A break-down of the latter figure would undoubtedly show much larger tonnages for the various uses enumerated. In 1935, 688 tons of zinc sulphate were used as a flotation reagent, according to data collected by T. H. Miller of the Bureau of Mines.

RAW MATERIALS USED IN THE MANUFACTURE OF LEAD AND ZINC PIGMENTS AND SALTS

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and miscellaneous secondary materials, such as scrap and waste from various industrial processes. In 1936, 93.2 percent of the lead in lead pigments was derived from pig lead and 6.8 percent from ore. Only a few tons were derived from secondary material. The proportions for zinc pigments in 1936 were 63 percent from ore, 22 percent from slab zinc, and 15 percent from secondary materials.

Metal content of lead and zinc pigments produced by domestic manufacturers, 1935-36, by sources, in short tons

	197, 404	132, 017	220, 096	150, 510

¹ Includes also lead recovered in zinc oxide and leaded zinc oxide.

² Zinc ashes, skimmings, drosses, and old metal.

In the following tables the source of the metal used in the manufacture of each pigment and salt is given. Pig lead is used exclusively, either directly or indirectly, in the manufacture of white lead, litharge, red lead, and orange mineral and to a large extent in the manufacture of basic lead sulphate. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in the manufacture of zinc oxide, leaded zinc oxide, lithopone, zinc sulphate, and basic lead sulphate. Some secondary lead is used in the manufacture of basic lead sulphate, and a substantial proportion of the zinc in lithopone and zinc chloride made in the United States is derived from secondary material. There has been a large increase in the quantity of secondary zinc used in the manufacture of zinc oxide since 1933. This material has displaced slab zinc in the manufacture of the French-process oxide.

PRICES

The total value and the average price received by producers from sales of lead and zinc pigments and salts are stated earlier in this chapter. The range of market quotations, as reported by the Oil, Paint, and Drug Reporter, appears in the following table. Quotations on lead pigments were advanced as the price of lead moved upward during the latter part of 1936. On October 1, zinc oxide prices were advanced by one-fourth cent per pound but were still considerably out of line with the price of the metal. A drop of 1 cent per pound in the price of titanium dioxide on November 2 was followed shortly by a reduction of one-fourth cent per pound in lithopone prices and 1½- to 2¼-cent cuts in zinc sulphide quotations.

Range of quotations on lead pigments and zinc pigments and salts at New York (or delivered in the East), 1933-36, in cents per pound

FOREIGN TRADE ²

Imports of lead and zinc pigments and salts declined 16 percent and exports increased 3 percent in 1936. The export surplus increased from \$452,000 to \$572,000; in 1929 it was over \$3,000,000. In 1933 there was an apparent import surplus.

The following table shows the value of the various pigments and salts imported and exported for 1935-36.

Value of foreign trade of the United States in lead and zinc pigments and salts, 1935-36

	1935		1936

GOLD, SILVER, COPPER, AND LEAD IN ALASKA

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary.....	225	Markets and shippers.....	226
Calculation of value of metal production.....	225	Company reports.....	228

The total output of gold, silver, copper, and lead from Alaska ores and gravels in 1936, in terms of recovered and estimated recoverable metals, was 539,162.60 fine ounces of gold, 427,592 fine ounces of silver, 29,166,000 pounds of copper, and 1,882,000 pounds of lead. This output compares with a production of 469,495.00 ounces of gold, 286,848 ounces of silver, 15,500,000 pounds of copper, and 1,340,000 pounds of lead in 1935.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464 + per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932–36

Year	Gold	Silver	Copper	Lead	Zinc
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>

¹ \$20.671835.

² \$0.64646464.

¹ The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in *Minerals Yearbook*, 1934, pp. 25–28.

Mine production of gold, silver, copper, and lead in Alaska, 1934-36, in terms of recovered metals

Year	Gold (lode and placer)		Silver (lode and placer)		Copper		Lead		Total value

MARKETS AND SHIPPERS

There are no smelters or refineries in Alaska. The bulk of the gold produced in 1936 was in the form of bullion from placer and lode mines sent to United States mints and assay offices. The bulk of the silver was contained in concentrates and high-grade ore shipped to the Selby (Calif.) and Tacoma (Wash.) smelters. Because of the transportation cost, all concentrates are high-grade.

Most of the copper in 1936 was contained in copper-silver ore and concentrates from the Kennecott Copper Corporation and Mother Lode Coalition Mines Co. at Kennecott. Other contributors of copper (as copper-gold-silver concentrates) were the Alaska Gold & Metals Co. at Ketchikan and the Nabesna Mining Co. at Chitina. The bulk of the lead production in 1936 was contained in lead-silver-gold concentrates from the Alaska Juneau Gold Mining Co. amalgamation-concentration mill at Juneau. Small tonnages of gold-silver concentrate were shipped by the Alaska Empire Gold Mining Co., Hawks Inlet; Chichagoff Mining Co., Chichagof; Golden Horn Mining Co., Iditarod; Gold Cord Development Co., Wasilla; Gold Helm Mining Co., Ketchikan; Fern Gold Leasing Co., Wasilla; Gold Standard Mines, Helm Bay; Hirst-Chichagoff Mining Co., Kimshan Cove; and Nukalaska Mining Co., Seward.

The total receipts from Alaska at the San Francisco Mint during 1936 were 8,900 fine ounces of gold and 1,362 fine ounces of silver, a large part of which came from C. J. Berry Dredging Co., Miller House district, and J. R. Murphy, lessee of the dredge (3-cubic foot buckets) of the Fairbanks Gold Dredging Corporation, Ltd., at Fairbanks; other large depositors were the Felder & Gale dredge (27 2½-cubic foot buckets) on Yankee Creek 16 miles from Takotna, and the H. J. Haney Mining Co. on Jerome Creek. The United States Smelting, Refining & Mining Co., Midvale, Utah, received a small amount of bullion from its subsidiary, the Fairbanks Exploration Co.; the Seattle Assay Office received the bulk of the bullion from this company.

The United States Assay Office, Seattle, Wash., reports the following receipts from Alaska in 1936:

Bullion of Alaskan origin deposited at United States Assay Office, Seattle, Wash., during year ended Dec. 31, 1936, in fine ounces

District	Gold	Silver	District	Gold	Silver
Circle-----	4, 349. 571	571. 24	Kuskokwim-----	7, 897. 297	824. 06

Eagle-----	5, 847. 149	1, 050. 72	Tanana-----	167, 655. 884	23, 068. 97
Iditarod-----	28, 111. 124	4, 246. 05			
Koyukuk-----	1, 476. 018	131. 06		481, 905. 768	69, 953. 28

Important shippers of bullion to the Seattle Assay Office in 1936 were: Alaska Empire Gold Mining Co. (Juneau), Alaska Juneau Gold Mining Co. (Juneau), Chichagoff Mining Co. (Chichagof), and Hirst-Chichagoff Mining Co., Kimshan Cove, all located in Southeastern Alaska; Alaska Gold Dredging Corporation (Dawson), American Creek Operating Co. (Fairbanks), Gold Placers, Inc. (Fairbanks), Ganes Creek Dredging Co. (Ophir), Nabesna Mining Co. (Chitina), Olson & Co. (Flat), Fairbanks Exploration Co. (Fairbanks), and the Walker's Fork Gold Corporation (Walker's Fork), all in the Yukon Basin region; Hammon Consolidated Gold Fields (Nome), in the Seward Peninsula region; Arctic Circle Exploration Co. (Candle), in the Kenai Peninsula region; Cripple Creek Mining Co. (Anchorage), Fern Gold Leasing Co. (Wasilla), and Willow Creek Mines, Inc. (Lucky-shot), all in the Cook Inlet-Susitna region; and the Chititu Mines (McCarthy), in the Copper River region. The Miners & Merchants Bank of Iditarod at Flat was agent for large quantities of bullion from the Iditarod district, Yukon Basin region. The Miners & Merchants Bank of Alaska at Nome bought large quantities of gold from the Nome, Bluff, Candle, Council, Inmachuk, Kougarek, Haycock, Teller, Solomon, and Bonanza districts, all in the Yukon Basin and Seward Peninsula regions. Other bullion buyers who served their respective regions were: Bank of Seward, Seward Peninsula region; First National Bank of Cordova and First National Bank of Valdez, Cook Inlet-Susitna region; and First National Bank of Fairbanks, Yukon Basin region. Several smaller bullion buyers, scattered throughout the different mining regions, purchased small lots and in turn sold the bullion to the larger buyers.

The Willow Creek Mines, Inc., was a regular shipper of bars throughout 1936 from its Lucky Shot mine on Craigie Creek in the Willow Creek district at the head of Cook Inlet, in the Cook Inlet-Susitna region.

The Alaska Gold & Metals Co. continued to produce palladium in 1936 with its gold-silver-copper concentrates.

The bullion produced by 38 floating dredges located almost entirely in two regions, the Seward Peninsula and Yukon River Basin, constituted 47 percent of the Alaska gold production for 1936. The operation of these dredges is limited to 4 to 8 months of actual mining during the late spring, summer, and early fall months. The sources of this production are bench, river, and beach deposits.

Compared with the dredge output the production of gold from the lode mines is second in importance. While the lode mines are scattered throughout the entire Territory, the principal producers are located in the Southeastern Alaska region, Cook Inlet-Susitna region, and Yukon Basin region. The production from the lode mines is, for the most part, continuous throughout the year.

The total gold production from dragline scraper, hydraulic, and many small sluicing operations represents 18 percent of the Territory's total but is the most widespread geographically.

Of the silver production, 86 percent was contained in the copper-silver ore and concentrates from the Kennecott Copper Corporation in the Copper River region and as a byproduct in the bullion and concentrates produced by the Alaska Juneau Gold Mining Co. in Southeastern Alaska. The remainder was a byproduct of lode and placer gold bullion.

The Kuskokwim River region has produced much platinum, most of it from the operations of the Goodnews Bay Mining Co., located in the Goodnews Bay mining district of this region. Other small amounts of platinum have been produced from the small placer operations.

The production of the rarer metals of the platinum-iridium group was small in 1936 and confined mostly to the placer and lode mines of the Kuskokwim River region and Southeastern Alaska.

COMPANY REPORTS

The Thirty-First Annual Report of the United States Smelting, Refining & Mining Co. for the year ended December 31, 1936, contains the following comments on its Alaska operations.

At Fairbanks, Alaska, dredging operations started on March 20th, with all five of the dredges in operation by March 27th. Aggregate number of dredge days was 1,252 in 1936, compared with 1,268 in 1935. Grade was slightly lower; but an increase in the yardage handled resulted in higher gold output. A normal water supply for the season permitted the required stripping and thawing ahead of the dredges. The additional power unit to provide power for the equipment, preparation and handling of the newly acquired dredging areas, referred to in last year's report, was completed during the year; and good progress has been made in the preparation of these areas. Further proven gravel reserves were acquired during the year.

Weather conditions at Nome, Alaska, permitted an earlier start than in 1935, one of the dredges starting on May 17th, another on May 21st and the last one on June 19th. Aggregate number of dredge days was 515 compared with 449 for the previous season. Considerably more gravel was dredged; and with grade about the same, the gold output was materially increased.

The Twenty-Second Annual Report of the Alaska Juneau Gold Mining Co. for the year ended December 31, 1936 (dated Mar. 3, 1937), says—

The operating profit for the year 1936, before deductions for depreciation and Federal income tax, was \$2,640,085.03. The substantial increase in operating profits over those of the previous year was due in greater part to an increase in yield of 8¢ per ton trammed, and in lesser part to an increased tonnage output. In 1935 the tonnage production suffered by time lost through a strike, and the increase in tonnage production in 1936 is due more to that fact than to a small increase in the rate of production per day of actual operation.

Three new stopes were completed and brought into production during the year, two in the North Orebody above Gold Creek Tunnel level, and one in the Perseverance area. The South Orebody stopes are now relieved from carrying the burden of production through the winter months under weather conditions that have been becoming more adverse in their effects each winter.

The two stopes located in the North Orebody area are continuations of other stopes in that area and the grade of ore to be mined here is well established. The grade of ore produced so far from the Perseverance stope is somewhat less than the average grade of South Orebody ore, all in accordance with expectations. The second stope in the Perseverance area will be brought into production this coming fall.

To continue the program for prospecting the lower levels of the mine, the No. 53 Prospect Winze has been sunk to a point 1,518 feet below the Gold Creek Tunnel level. A station has been cut at the No. 13 level and crosscutting through the ore horizon will be started this year.

A drainage tunnel was started and is being driven below and parallel to Gold Creek Tunnel, for the purpose of handling the water that comes into the mine in increasing amounts each year, through the South Orebody stopes, which have long since caved through to the surface.

Although gold production is expected to continue at about the 1936 yearly rate, increased taxation, Territorial, State and Federal, together with increasing prices of commodities, will have a tendency to effect a reduction in the amount of surplus earnings over and above the present dividend rate.

The work of developing and preparing the Perseverance section for mining was continued throughout the year. No. 470 stope, the first stope in this section, started 65 feet above the No. 4 main Gold Creek Tunnel level. Thirty-one thousand eighty-seven square feet of stope cutout was done, and the stope was in production at the end of the year. In addition, 745 feet of main haulage level, 722 feet of main oreways, together with 7,752 feet of auxiliary raises and intermediate levels, were driven. Several pieces of this work made connections with old Perseverance levels that are still open, thereby providing excellent ventilation for this area.

In the 53 winze area of the North Orebody the usual preparatory work was done both above and below the No. 4 level, and in addition the 53 winze, which has a slope of 60° from the horizontal, was sunk an additional 432 feet to a vertical depth of 1,518 feet below the main haulage level.

A station was cut in the winze and crosscutting was started on the 13 level, 450 feet below the previous lowest level, and 1,450 feet vertically below the main haulage level.

During the year, 193,100 pounds of powder were used in blasting powder drifts and 104,000 pounds were used in blasting long hole drill stations, making a total of 297,100 pounds for primary breaking, or 0.07 pound per ton trammed. The total powder consumption for mining was 0.30 pound per ton trammed as against 0.32 pound in 1935, and 0.28 pound in 1934.

Mill.—Experimental work, mentioned in last year's report having shown that a profit could be made by fine grinding and treating by flotation a certain portion of the fine tailings, was expanded into a regular part of mill operation. Five hundred tons of the coarser portion of the fine tailings are reground daily and treated by flotation, resulting in an additional profit of \$50,000.00 during 1936 from this source. Further experimental work to recover values from the mill slimes is now under way. Results do not as yet justify a prediction as to whether this can be profitably done. Experimental work along this line will be continued and if profitable results are proved, appropriate installations of equipment will be made.

Labor.—There was an abundant supply of labor of all kinds throughout the year. The labor turnover during the year was very small. The six day work week adopted in 1934 has been continuously in effect since that time. The average daily wage for the year was \$6.15 and the overall cost per man per day was \$10.04.

Power plants.—The work of rebuilding the 2-mile flume and the rehabilitation of Salmon Creek No. 1 power plant was completed during the year. The rehabilitation of the plant has taken two seasons' work, the total cost having been \$130,000.00. The plant was put in operation at the beginning of the 1936-37 winter season. The additional power supplied by this plant will make it unnecessary to run the steam plant except for a short time during peak loads in the longest, coldest winters or when line trouble on the mountain prevents transmission of power from the Annex Creek plant.

The small wooden dam at the Annex Creek Reservoir was rebuilt and an additional 5 feet was added to its height, giving additional storage for water equivalent to 1 million kilowatt-hours of power.

Gold content of ore from Alaska Juneau mine in 1936, by months

¹ Lost in tailings.

The Kennecott Copper Corporation operated its Kennecott property and mill and the adjoining Mother Lode Coalition Mines Co. property part of the year 1936. The Twenty-Second Annual Report of the

Kennecott Copper Corporation for the year ended December 1936 does not divide the Alaska output from the Utah and Nevada production but reaffirms the belief "that operations will cease in not more than 2 years, due to inability to find new ore bodies."

The Eighteenth Annual Report of the Mother Lode Coalition Mines Co. for the year ended December 31, 1936 (dated Mar. 12, 1937), says—

Operations at the mine were continued on a curtailed basis during the first part of the year but as the demand for and price of copper increased output was gradually raised.

There were received for treatment at the Tacoma Smelter during the year 15,454,983 pounds of copper. Due to the maritime strike on the Pacific Coast no shipments of ore or concentrates could be made from Alaska during November and December. The gross amount realized from metal sales was \$950,240.90. After the addition of miscellaneous income and the deduction of all costs, including taxes, the net income of the company, before depletion, amounted to \$403,532.93. A cash distribution of 12½ cents per share was made to stockholders December 21, 1936.

As has been repeatedly pointed out to you in previous annual reports, while development and prospecting work has been carried on, except during those years when the mine was shut down, the results have been most unfavorable and disappointing and no new ore bodies of commercial grade have been disclosed during the past 13 years. In view of the consequent depletion of the company's ore reserves and the short life of the mine indicated as still remaining, it was believed advisable by the management to secure the services of an independent mining engineer to make a thorough examination of the company's property. Mr. L. A. Levensaler was engaged for this purpose and in September of last year he extensively examined the property, particularly with respect to the scope of development and prospecting work already done, the advisability of its continuance, and the extent of the ore reserves still remaining in the mine.

Mr. Levensaler's examination confirmed the reports of the company's own engineers. He has advised that a careful examination of the developed area of the mine revealed that no commercial ore remains except as backs of drifts, sill floors and pillars within the stoped section between the 1,000- and the 1,400-foot levels. Mr. Levensaler advised that after the reclamation of these blocks of ore the mine will necessarily have to be abandoned. He further advised that the remaining development possibilities of the mine are too weak to justify prospecting and should be dropped from consideration.

A complete recalculation of all the known ore reserves was made by the company's engineers in conjunction with Mr. Levensaler. It is estimated that there were remaining in the mine on January 1, 1937, 2,589 tons of high grade ore containing 1,605 tons of copper, and 65,743 tons of milling ore containing 7,639 tons of copper, a total of 68,332 tons of ore with a copper content of 9,244 tons, of which some 8,000 tons should be recovered after allowing for probable losses in concentration. There had been produced and were awaiting shipment to the smelter on January 1, 1937, 5,039 tons of ore and concentrates containing 2,714 tons of copper. In addition, there were on hand, refined and in process, unsold at the smelter, 5,223 tons of copper. Consequently, on January 1, 1937, based upon the above estimate of remaining ore, the total quantity of copper still to be sold amounted to about 16,000 tons.

All present indications point to the life of the mine being extremely limited. No further prospecting seems justified. Therefore it is obvious that after the extraction of the small tonnage of ore still remaining the mine will have to be abandoned. The ore still left will be extracted at a rate judged most economical and the company's copper sold as deemed to its best advantage.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN ARIZONA ¹

(MINE REPORT)

By C. N. GERRY AND PAUL LUFF

SUMMARY OUTLINE

Calculation of value of metal production.....	233	Mining industry.....	240
Summary of 1935.....	237	Ore classification.....	240
Mine production by counties.....	239	Metallurgic industry.....	243
		Review by counties and districts.....	246

The value of the metal production of Arizona in 1936 (\$56,116,940) increased nearly 51 percent over 1935, due to the large increase in the quantity of all metals and in the prices of silver, copper, lead, and zinc. Most of the increase in value resulted from production and sales of copper; Arizona retained its place as the leading copper producer of the United States. The chief reasons for the higher production in 1936 were the increased activity in the Warren district, Cochise County; Ajo district, Pima County; Verde district, Yavapai County; Globe district, Gila County; and San Francisco district, Mohave County.

Arizona contains several of the largest well-developed and well-equipped copper-silver-gold mines in the United States. Three mines of the Phelps Dodge Corporation (Copper Queen at Bisbee, United Verde at Jerome, and New Cornelia at Ajo) produced nearly half of the State gold production; these three mines and the Magma mine produced 73 percent of the silver output. The recoverable gold output from mines in Arizona in 1936 was 310,000 ounces, the largest for 1 year ever recorded in the State and 68,245 ounces more than in 1935. The average annual output for the last decade was 175,588 ounces. At \$35 an ounce the value of the 1936 gold output was \$10,850,000 compared with \$8,461,411 in 1935.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price ²; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for

¹ Figures for 1936 are preliminary; detailed data with final revisions will be released later.

² The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in *Minerals Yearbook*, 1934, pp. 25-28.

newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ 7,000 ounces of gold produced at placer mines in 1936; other figures not yet available.

² Dragline and power-shovel excavators with sluices or special amalgamators.

Gold.—The recoverable gold output from mines in Arizona increased from 241,754.60 fine ounces in 1935 to 310,000 fine ounces in 1936. Gold from lode mines in 1936 was approximately 303,000 ounces compared with 236,597.60 ounces in 1935, and 7,000 ounces of gold were recovered from placers compared with 5,157.00 ounces in 1935. One floating dredge, equipped with power shovels but no buckets, was operated on Lynx Creek in 1936 as in 1935. Large increases in the production of gold in 1936 were shown by the United Verde, New Cornelia, Copper Queen Branch of the Phelps Dodge Corporation, Tom Reed, Pilgrim (Pioneer), Gold Standard, Shattuck-Denn, Mammoth-St. Anthony, Hillside, Pioneer, Bi-Metal, and Gold Road mines. Eleven mines in Arizona produced more than 5,000 ounces of gold each in 1936—the Copper Queen Branch at Bisbee, United Verde Branch at Jerome, New Cornelia Branch at Ajo, Tom Reed at Oatman, Hillside near Hillside, Magma at Superior, Portland at Katherine, Pioneer near Chloride, Octave near Congress Junction, Montana Mines Operations at Ruby, and Mammoth-St. Anthony at Mammoth. Other mines that produced more than 4,000 ounces of gold each in 1936 were the Harbud, United Verde Extension, Amulet (Pioneer), Lynx Creek dredge, and Shattuck-Denn mines. The construction of a new mill of importance in gold recovery was completed at the Gold Road property of the United States Smelting, Refining & Mining Co. near Oatman.

Silver.—The recoverable silver output increased from 6,601,280 ounces in 1935 to about 8,125,100 ounces in 1936 and the value from \$4,744,670 to \$6,292,890, as the average price of silver rose from 71.875 cents an ounce in 1935 to 77.45 cents in 1936. The average annual output for the last 10 years has been 5,361,630 ounces. More than 73 percent of the total silver produced in Arizona in 1936 was recovered from copper ore, chiefly from the Copper Queen, United Verde, Magma, and New Cornelia mines; most of the remainder was recovered from lead-zinc ore and siliceous ores. The Copper Queen and United Verde mines of the Phelps Dodge Corporation produced more than 56 percent of the State's silver. Other large producers of silver were the Eagle-Picher, Magma, New Cornelia, Hillside, United Verde Extension, Tombstone, Reymert, Miami, Shattuck-Denn, Swastica, and Arizona Magma properties.

The Warren (Bisbee) district in Cochise County increased its production of silver from 2,654,731 ounces in 1935 to about 3,260,000 in 1936; the Verde district in Yavapai County, from 1,049,934 ounces to 1,675,000; and the Pioneer (Superior) district in Pinal County, from 802,944 ounces to 805,000. However, the output of silver from the Oro Blanco (Ruby) district in Santa Cruz County dropped from 670,944 to 630,000 ounces.

Copper.—The recoverable copper output in 1936 was 409,200,000 pounds, the largest output since 1930, when 576,190,607 pounds were produced, and slightly greater than in 1931, when the production was 401,344,909 pounds. The largest yearly production was in 1929 (830,628,411 pounds) and the next largest in 1918 (764,855,874 pounds). The increase in 1936 over 1935 was 131,170,711 pounds, and the value increased from \$23,076,431 to \$37,646,400. The copper smelters at Douglas, Clarkdale, and Superior continued operations during 1936, and the receipts of ore and concentrates were considerably more than in 1935. The smelter at Clemenceau operated intermittently, but the smelters at Clifton and Hayden remained idle. The

New Cornelia mine of the Phelps Dodge Corporation at Ajo was again the largest producer of copper in Arizona; it was followed by the United Verde mine at Jerome and the Copper Queen mine at Bisbee (both operated by the Phelps Dodge Corporation), the Inspiration mine at Inspiration, the Miami mine at Miami, and the Magma mine at Superior. These six properties produced approximately 387,600,000 pounds of copper (nearly 95 percent of the State total), and each produced more than 30,000,000 pounds of copper. Other large producers of copper were the United Verde Extension, Shattuck-Denn, and Bagdad properties. The entire output of copper from the United Verde mine came from steam-shovel operations in the open pit, as no attempt is being made at present to mine ore from the deep levels of the property.

The Globe (Inspiration-Miami) district was the chief copper-producing district in Arizona in 1936, as the output increased from 37,359,120 pounds in 1935 to 109,150,000 in 1936; the Ajo district, with an increased production, ranked second; the Verde district, with a greatly increased production, ranked third; the Warren (Bisbee) district, with a production of about 78,600,000 pounds, ranked fourth; and the Pioneer (Superior) district, with a production of 30,150,000 pounds, ranked fifth.

Lead.—The recoverable lead production in Arizona increased from 15,566,100 pounds in 1935 to 20,275,000 in 1936, the largest production since 1926, when 23,258,274 pounds were produced. The value of the lead output in 1936 was \$932,650 compared with \$622,644 in 1935. The large gain in the production of lead in Arizona in 1936 was due chiefly to the increase in shipments of lead ore from the "79" mine near Winkelman and the Shattuck-Denn mine at Bisbee and to the reopening of the Tennessee-Schuylkill lead-zinc mine at Chloride and the Trench and Flux lead-silver mines near Patagonia. The Eagle-Picher Mining & Smelting Co. in 1936 was again by far the largest producer of lead in Arizona; it was followed by the "79", Trench (Gold Canyon Mining Co.), Tennessee-Schuylkill, Shattuck-Denn, Tombstone (Bunker Hill property including Toughnut lease), Hillside, Flux, and Copper Queen mines. These nine properties produced 91 percent of the State output of lead.

Zinc.—In 1934 and 1935 nearly all the zinc produced in Arizona came from the Montana property of the Eagle-Picher Mining & Smelting Co. at Ruby, Santa Cruz County. In August 1936 the Tennessee-Schuylkill group at Chloride, Mohave County, was reopened, and in September the 150-ton flotation-concentration plant started treating lead-zinc ore. The output of recoverable zinc in Arizona in 1936 was about 7,900,000 pounds valued at \$395,000, compared with 6,673,932 pounds valued at \$293,653 in 1935. As usual, the Eagle-Picher Mining & Smelting Co. was the largest producer of lead and zinc in Arizona and ranked third in the production of silver. The company operated its 250-ton flotation-concentration plant continuously and treated more lead-zinc ore in 1936 than in 1935.

Ore.—The output of ore in Arizona in 1936 was approximately 12,800,000 tons, an increase of 6,029,950 tons over 1935. Copper ore increased from 6,011,755 to 11,880,000 tons, gold (ore and old tailings) and gold and silver ore from 578,405 to 705,000 tons, silver ore from 26,239 to 32,000 tons, lead ore from 16,749 to 29,000 tons, and lead-zinc ore from 129,772 to 155,000 tons. There were large increases in

the output of copper ore from the Globe (Miami-Inspiration), Ajo, Verde, and Warren districts and in gold ore from the San Francisco (Oatman and Portland), Old Hat (Mammoth), and McConnico districts, but the output of ore from the Katherine district decreased considerably. Virtually the entire output from the Vulture district in 1936 was old tailings (gold) from the Vulture property which increased from 34,661 to about 100,000 tons. The New Cornelia, Miami, Inspiration, United Verde, Copper Queen, and Magma mines were the chief producers of copper ore; the Tom Reed, Hillside, Harbud, Portland, New Year-Mohawk, Mammoth-St. Anthony, Pilgrim, Golden Turkey, and Octave mines were the chief producers of gold ore; the Reymert mine was the largest producer of silver ore; the Arizona Magma property was the largest producer of gold and silver ore; the "79" mine was the largest producer of lead ore; and the Eagle-Picher property was the largest producer of lead-zinc ore.

SUMMARY OF 1935

Final annual figures on mine production in Arizona in 1935 and detailed statistics on production by classes of ore, methods of recovery of metals, and mining districts, continuing the series published in recent years in the Statistical Appendix to Minerals Yearbook, are included in this chapter.

From 1903 to the end of 1935 mines in Arizona have produced 358,865,867 tons of ore, 5,930,896.91 fine ounces of gold, 153,915,125 fine ounces of silver, 14,506,097,660 pounds of copper, 377,995,472 pounds of lead, and 146,428,497 pounds of zinc.

Gold.—The output of gold in Arizona in 1935 was 241,754.60 fine ounces, more than double the output (167,024.12 ounces) in 1934. Gold recovered at placers amounted to 5,157.00 ounces (1,825.26 ounces less than in 1934) and accounted for more than 2 percent of the State total; most of the placer output resulted from operation of the floating dredge on Lynx Creek by the Lynx Creek Placer Mine Co. and other operations in Yavapai County.

Gold recovered from lode mines was 236,597.60 fine ounces, of which 112,783.79 ounces came from copper ore and 112,266.75 from siliceous ore, chiefly gold ore. In 1934 copper ore supplied 76,092.34 ounces and siliceous ore 77,949.51 ounces. Gold from bullion recovered by amalgamation or cyanidation increased from 36,828.30 ounces in 1934 to 43,815.72 in 1935; most of the increase came from Mohave County. The Copper Queen Branch of the Phelps Dodge Corporation was by far the largest producer of gold in Arizona in 1935; it was followed by the United Verde Branch at Jerome and the New Cornelia Branch at Ajo, both operated by the Phelps Dodge Corporation. Other large producers of gold were the Tom Reed at Oatman, Magma at Superior, Eagle-Picher at Ruby, and Hillside near Hillside. These seven properties produced 129,700 ounces of gold or nearly 54 percent of the total output of the State.

Silver.—The output of silver increased 48 percent over that in 1934, and most of it (69 percent) was recovered from copper ore; the remainder was recovered chiefly from siliceous ore and lead-zinc ore. Nearly 62 percent of the State output of silver in 1935 came from the Copper Queen Branch at Bisbee, United Verde at Jerome, Eagle-Picher at Ruby, Magma at Superior, New Cornelia at Ajo, United Verde Extension at Jerome, and the Hillside north of Hillside.

Copper.—The output of copper in Arizona was 278,029,289 pounds in 1935, compared with 178,082,213 pounds in 1934, an increase of 56 percent. Of the total copper produced in Arizona in 1935, 276,469,902 pounds were recovered from copper ore and 67 percent came from 3 mines operated by the Phelps Dodge Corporation. The largest producer of copper in Arizona in 1935 was the New Cornelia mine; it was followed by the Copper Queen, United Verde, Magma, Miami, and United Verde Extension mines. The total value of the metals recovered from copper ore and precipitates was \$30,161,989—81 percent of the total value of the gold, silver, copper, lead, and zinc produced in the State.

Lead.—The output of lead in Arizona in 1935 was 15,566,100 pounds, more than double the output (6,877,216 pounds) in 1934. The large increase in 1935 was due chiefly to the increase in the production of lead-zinc ore from the Eagle-Picher property at Ruby and lead ore from the "79" mine near Hayden Junction. Nearly 61 percent of the total lead was recovered from lead-zinc ore, 30 percent from lead ore, and 7 percent from siliceous gold ore. The Eagle-Picher Mining & Smelting Co. was, as usual, the largest producer of lead in Arizona; it was followed by the "79", Tombstone (Bunker Hill), and Tombstone Extension properties.

Zinc.—The output of zinc in Arizona was 6,673,932 pounds in 1935, compared with 1,810,279 pounds in 1934; no zinc was produced in 1931 or 1932. Nearly all the zinc produced in 1935 was recovered from lead-zinc ore from the property of the Eagle-Picher Mining & Smelting Co. at Ruby, Santa Cruz County; a little zinc was produced from a property north of Kingman, Mohave County.

MINING INDUSTRY

Compared with 1932-34 the mining industry of Arizona in 1935 showed marked improvement. The important features of 1935 were the reopening, in January, of the United Verde mine at Jerome; the reopening, in September, of the Inspiration Consolidated property at Inspiration; the marked increase in the production of copper ore from the New Cornelia and Miami mines; the large gain in the output of siliceous gold ore from mines at Oatman, Katherine, Mammoth, Hillside, Cordes, and Octave; and the increase in the output of lead-zinc ore from Ruby, Santa Cruz County.

ORE CLASSIFICATION

Ore sold or treated in Arizona in 1935, with content in terms of recovered metals

¹ A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

Dry and siliceous ore.—The output of dry and siliceous ore was 604,644 tons from 780 properties in 1935, compared with 373,073 tons from 622 properties in 1934.

Copper ore.—Copper ore mined and treated totaled 6,011,755 tons from 82 properties in 1935, compared with 2,845,604 tons from 58 properties in 1934.

Lead ore.—The output of lead ore was 16,749 tons from 67 properties in 1935, compared with 16,203 tons of ore from 87 properties in 1934.

Copper-lead ore.—There were three small producers of copper-lead ore in 1935 and six in 1934. The output (4 tons) in 1935 was ore of smelting grade and came from sample lots from Pima and Santa Cruz Counties.

Lead-zinc ore.—Two mines (one in Santa Cruz County and one in Mohave County) produced 129,772 tons of lead-zinc ore in 1935 compared with two properties producing 35,315 tons in 1934.

Ore sold or treated in Arizona in 1935, by counties, with content in terms of recovered metals

METALLURGIC INDUSTRY

Of the total ore and old tailings produced in 1935 in Arizona, 4,815,612 tons were treated at concentration plants, 1,350,679 tons represented crude ore smelted, and 271,910 tons were treated at gold and silver mills; no ore was treated by straight leaching.

The following table summarizes data for operations at gold and silver mills in 1935, by counties.

Mine production of metals from gold and silver mills in Arizona in 1935, by counties, in terms of recovered metals

 * Includes items entered as "(?)" above.

The high price of gold continued to cause a large gain in the number of both lode and placer producers in Arizona in 1935 and in the quantity of siliceous gold ore treated. The number of producing lode mines increased from 747 in 1934 to 904 in 1935 and the placer producers from 867 to 1,197. The output of gold ore was 492,213 tons from 651 properties in 1935 compared with 344,910 tons from 528 properties in 1934. The tonnage of copper ore mined and treated was 6,011,755 tons (nearly 89 percent of the State output) from 82 properties in 1935 compared with 2,845,604 tons from 58 properties in 1934. There were 150 producing districts in Arizona in 1935, and the Warren (Bisbee) district again led in value of output. It had the following production: Ore, 600,659 tons; gold, 56,161.54 ounces; silver, 2,654,731 ounces; copper, 64,562,530 pounds; and lead, 399,925 pounds. The value of the four metals was \$9,248,429.

The output of the Tombstone district increased slightly; the chief output was from the Tombstone (Bunker Hill) property.

In the Globe-Miami district the output of ore increased to 1,171,101 tons, chiefly from the Miami mine.

In the Oatman, Katherine, and Portland regions of the San Francisco district, Mohave County, the increase in siliceous gold ore produced was notable.

At Ajo the New Cornelia Branch of the Phelps Dodge Corporation operated throughout the year; it was the largest producer of copper in the State.

At Superior in the Pioneer district the mine and smelter of the Magma Copper Co. were active, and a large production of gold, silver, and copper resulted. The Lake Superior & Arizona lease was a large producer of gold. In the Old Hat district in Pinal County considerable gold, chiefly from concentrates, was recovered at the New Year-Mohawk and Mammoth-St. Anthony mines.

The Eagle-Picher Mining & Smelting Co. operated its mine and mill at Ruby throughout the year; it was a large producer of silver, lead, and zinc.

In the Verde district the United Verde Copper Co., formerly the largest producer of copper, silver, and gold in Arizona, was again operated in January. The United Verde Extension continued operations but at a greatly reduced rate.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA

The output of gold, silver, copper, lead, and zinc from California ores, gravels, and re-treated tailings in 1936, in terms of recovered metals, was 1,077,442 fine ounces of gold valued at \$37,710,470; 2,103,799 fine ounces of silver valued at \$1,629,392; 8,762,000 pounds of copper valued at \$806,104; 964,000 pounds of lead valued at \$44,344; and 16,000 pounds of zinc valued at \$800—a total of \$40,191,110 for the five metals. In 1935 California mines yielded 890,430 ounces of gold valued at \$31,165,050; 1,191,112 ounces of silver valued at \$856,112; 1,954,000 pounds of copper valued at \$162,182; 1,134,000 pounds of lead valued at \$45,360; and 322,000 pounds of zinc valued at \$14,168—a total of \$32,242,872. The quantity and value of all the metals except lead and zinc increased substantially. Gold increased 21 percent in both quantity and value, silver 77 percent in quantity and 90 percent in value, and copper 348 percent in quantity and 397 percent in value; lead decreased 15 percent in quantity and 2 percent in value and zinc 95 percent in both quantity and value. The value of the five metals increased 25 percent in 1936 over 1935. Moreover, the upward trend in quantity production carried the total value of the metals above that in any year since 1862. Gold comprised 94 percent and silver 4 percent of the total value of the five metals; the remaining 2 percent was accredited almost entirely to copper. The enormous production of gold in the Grass Valley-Nevada City district was the principal factor in maintaining Nevada County in first position among the nonferrous metal-producing counties of the State, but a very large output was also reported from

¹ The assistance of O. Y. Sharman is acknowledged.

a number of other counties. In Sacramento, Yuba, and Merced Counties gold dredges produced great quantities of gold. The two deepest lode mines in the State, the Argonaut and the Kennedy, are situated on the Mother Lode in Amador County. In addition to Amador County the other four Mother Lode counties—Eldorado, Calaveras, Tuolumne, and Mariposa—each continued in 1936 to have many operating lode-gold mines; and in Plumas County the Walker mine again produced large quantities of copper. In the southern part of the State the increasing output of the Mojave district restored Kern County to its former place as a leading gold producer.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price²; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

² The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25–28.

Gold.—The production of recoverable gold in California was 1,077,442 fine ounces valued at \$37,710,470 in 1936—an increase of 21 percent in quantity and value over 1935. Lode mines produced 668,019 ounces of gold valued at \$23,380,665 or 62 percent of the total gold; placer mines produced 409,423 ounces of gold valued at \$14,329,805 or 38 percent of the total. In 1935 lode mines produced 61 percent and placer mines 39 percent of the total, and in 1934 the percentages were 62 and 38 percent, respectively. There follows a list of companies (or mines) operating lode-gold mines, arranged roughly in their order of importance as producers: Empire Star Mines Co., Ltd. (Nevada County), Idaho Maryland Mines Corporation (Nevada County), Lava Cap Gold Mining Corporation (Nevada County), Golden Queen Mining Co. (Kern County), Kennedy Mining & Milling Co. (Amador County), Argonaut Mining Co., Ltd. (Amador County), the Iron Mountain property of the Mountain Copper Co., Ltd. (Shasta County), the Big Canyon property of the Mountain Copper Co., Ltd. (Eldorado County), the Carson Hill Gold Mining Co. (Calaveras County), Cardinal Gold Mining Co. (Inyo County), Original Sixteen to One Mine, Inc. (Sierra County), the Yellow Aster mine of the Anglo American Mining Corporation (Kern County), Walker Mining Co. (Plumas County), and Tropico mine operated by Burton Bros., Inc. (Kern County). The following were the leading gold producers from placers in California, arranged roughly in order of their output in 1936: Yuba Consolidated Gold Fields (Yuba County), Natomas Co. (Sacramento County), Capital Dredging Co. (Sacramento County), Snelling Gold Dredging Co. (Merced County), Yuba Consolidated Gold Fields (Merced County), Arroyo Seco Gold Dredging Co. (Amador County), Gold Exploration Mining Co. (Yuba County), and the Comanche Gold Dredging Co. (Calaveras County). The lode and placer mines listed produced over three-fifths of the State's total gold. In all, there were 903 lode and 639 placer mines operating during the year. Since the depression many people lacking other employment have panned gold by hand in the streams of California with the hope of extracting enough to furnish the bare necessities of life. Although the average income of this class of miners has been small, a few of the more fortunate ones have discovered rich pockets. A special study of the 1935 production of the small-scale placer-gold miners was made by the Bureau during the year in cooperation with the Works Progress Administration. The miners usually worked ground they did not own. The total output for 1935 exceeded \$1,000,000 and over 19,000 men were thus engaged at some time during the year. Although definite figures are not available for 1936, it appears that this class of miners again contributed a large quantity of bullion to the State production. Greater employment opportunities in other fields appear to have somewhat decreased the number on the creeks; many, however, are still working on the streams.

Silver.—The production of recoverable silver in California was 2,103,799 fine ounces valued at \$1,629,392 in 1936 compared with 1,191,112 fine ounces valued at \$856,112 in 1935—an increase of 77 percent in quantity and 90 percent in value. The companies (or mines) producing the largest quantities of silver, in the approximate order of their importance, are as follows: Sierra Consolidated Mines, Inc. (Mono County), Walker Mining Co. (Plumas County), Golden Queen Mining Co. (Kern County), Lava Cap Gold Mining Corpora-

tion (Nevada County), Kelly mine (Kern County), and the Empire Star Mines Co., Ltd. (Nevada County). The Sierra Consolidated Mines, Inc., works its Silverado mine principally for silver, but the other leading silver producers derived the bulk of their revenue from other metals. The Walker mine was worked mainly for the copper content of its ores; the other mines listed were worked for gold. On the other hand, almost all the mines in the State derived at least a small amount of revenue from silver; even the gold dredges found the silver content of their bullion a profitable byproduct.

Copper.—The production of recoverable copper in California was 8,762,000 pounds valued at \$806,104 in 1936 compared with 1,954,000 pounds valued at \$162,182 in 1935—an increase of 348 percent in quantity and 397 percent in value. The Walker Mining Co. in Plumas County, reopened in August 1935, was by far the most important producer of copper ore in California during 1936 and made over nine-tenths of the State's output. Small quantities of copper were also derived from a number of gold ores, the metallurgical treatment of which included concentration and shipment of the concentrates for smelting.

Lead.—The production of recoverable lead in California was 964,000 pounds valued at \$44,344 in 1936 compared with 1,134,000 pounds valued at \$45,360 in 1935—a decrease of 15 percent in quantity and 2 percent in value. Inyo County continued to be the leading producer of lead-bearing ore, but considerable quantities of the metal were derived from gold concentrates, particularly in the Grass Valley-Nevada City district.

Zinc.—The production of recoverable zinc in California was 16,000 pounds valued at \$800 in 1936 compared with 322,000 pounds valued at \$14,168 in 1935—a decrease of 95 percent in both quantity and value. The only zinc producer in 1936 was the Blue Light mine in Orange County, and it was idle at the close of the year.

Gold and silver produced at placer mines in California, 1931-35, in terms of recovered metals

⁴ Includes all placer operations using power excavator and washing plant, both on dry land.

The production of gold in California represented more than 95 percent of the combined value of the gold, silver, copper, lead, and zinc output of the State for several years preceding 1936. During 1936, however, the revival of copper mining in Plumas County and the larger silver production in a number of areas, notably in Kern, Mono, and Napa Counties, caused the proportionate importance of gold to drop to 94 percent of the total value of the five metals. The production of gold, nevertheless, increased considerably during the year at both lode

and placer mines, and it appeared that the stimulating effect of the higher price for the metal had not yet run its course. Toward the close of the year, however, rising wages and higher material and supply costs began to make themselves felt. Along the Mother Lode a number of old mines were being reopened, and in the Mojave district of Kern County the exploration of the last 2 or 3 years began to yield substantial results.

At the placer mines of California, dredges of various types continued to produce the bulk of the gold recovery. Conventional dredges of the connected-bucket type increased their yield of gold by over 50,000 ounces compared with 1935 and yielded 71 percent of the placer-gold output of the State. Outstanding mining innovations of the last few years have been the developments of the dragline and dry-land dredges; the former produced over $1\frac{1}{2}$ times as much gold in 1936 as in 1935, and the latter more than doubled its output. The dredges classified as draglines are those having floating washing plants to which the auriferous gravel is delivered by the dragline type of power shovel. Plants have been classified as dry-land dredges when the washing plant has been mounted on dry land and the gravel to be treated has been excavated by mechanical means. On the other hand, production at hydraulic mines declined during the year to a little over one-half that for 1935, partly because of drought conditions in some of the hydraulic areas but probably more largely because of the application of legal restrictions. Production by small-scale hand methods decreased about 20 percent. Undoubtedly improved employment opportunities caused many of those following this means of livelihood to turn to other types of employment. Water shortage handicapped the small operators in some areas. The drift mines made a substantial increase in production as recorded.

MINE PRODUCTION BY COUNTIES

¹ Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

² Of total silver, 1,167,269 ounces were from lode mines and 23,903 ounces from placers.

³ Included under "Undistributed."

⁴ No information as to number (see footnote 1).

⁵ East Belt district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.

⁶ Mother Lode district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.

⁷ No information as to district of origin.

⁸ Exclusive of lode output, which is included under "Undistributed."

⁹ Exclusive of placer output, which is included under "Undistributed."

¹⁰ Randburg district lies in both Kern and San Bernardino Counties.

¹¹ Includes items entered as "(?)" above.

ALPINE COUNTY

Mogul-Monitor district.—The Zaca Mining Corporation operating the Zaca mine in 1936 milled a small quantity of gold-silver ore and shipped the concentrate for smelting.

AMADOR COUNTY

East Belt district.—The Amador Columbus Co. worked the Amador Columbus mine during the last 3 months of 1936. The Wiljobar Corporation developed the Defender mine in the Volcano section from August 4 to the end of the year. Ore and old tailings were treated by flotation at the Nottus mine. Gold ore from the Fort Ann mine was treated by amalgamation and concentration. Lessees worked the Grand Prize property near Pioneer from July 20 until the end of the year. Among the placer operations in the district were the Elephant mine worked by hydraulicking and the Bordeman property worked by dry-land dredging.

Ione district.—The Arroyo Seco Gold Dredging Co. operated two electric-powered connected-bucket dredges with a capacity of 6,000 and 2,000 cubic yards per 24 hours, respectively. The Buena Vista mine was worked under lease by the hydraulic method.

Mother Lode district.—The part of the Mother Lode district that passes through Amador County contains several of the largest and deepest gold mines of the State. The most important during 1936 were the Argonaut Mining Co., Ltd., Kennedy Mining & Milling Co., and the Central Eureka Mining Co. near Martell. The Argonaut Mining Co., Ltd., employed an average of 214 men throughout the year and in addition to its mine activities drove over 2,400 feet of development headings. The new 300-ton ball mill and flotation plant was tested during the summer and started continuous operations on August 27. Preparations were made for sinking to the 6,150-foot level during 1937; the mine was already the deepest in California.

The Kennedy mine derived the bulk of its tonnage during 1936 from its own old tailings pile but treated a considerable tonnage of ore from its mine. An average of 177 men was employed during the year. The Central Eureka Mining Co., worked the Old Eureka and Central Eureka mines. The Central Tailings Co. treated a large tonnage of old tailings from the Central Eureka dump by cyanidation. Another large tailings operation in the same area was that of the Delta Tailings Co., which cyanided a deposit of old tailings that had collected as a delta on one of the streams draining the Mother Lode district. The Amador Mother Lode Mining Co. started on August 10 with a crew of 30 men to rehabilitate the old Fremont and Gover mines near Drytown. An old stamp mill was repaired for testing the ore, and a 200-ton flotation plant was projected; there was no production during 1936. The Black Hills Mining Co. treated the ore from its mine in a five-stamp mill by amalgamation and concentration. A small quantity of very high-grade ore was reported from the Fuller mine. In addition to treating a large tonnage of ore in a 300-ton amalgamation and flotation plant, the Original Amador Gold Mines did over 3,200 feet of development work; an average of 80 men was employed throughout the year. Orr's custom mill treated ore derived from waste and prospect dumps; this 10-stamp mill equipped with amalgamation and concentration, was built during the year. Many

placer operations were reported in the district. Lessees operated a dry-land dredge at the Red Hill placer on the Vicini ranch for about 6 months.

BUTTE COUNTY

Forbestown district.—The Gold Bank, Golden Queen, and Midas developed by the Idaho Maryland Mines Corporation were the outstanding operations in the Forbestown district in 1936. Gold ore was treated by flotation and the concentrate trucked to the company concentrate cyanide plant at Grass Valley.

Magalia district.—Numerous miners worked both lode and placer properties in the Magalia district in 1936. A dry-land dredge at the Hintz mine on Butte Creek was one of the larger producers. Several mines, including the Bennett, Blue Channel, Blue Jay, Dally, Dix, and Emma, were in production.

Merrimac district.—Gold was produced at the Manzanita lode mine and the Last Chance placer claim during 1936.

Oroville district.—A dry-land dredge worked the Consuelo mine during 1936. The Butte Gold Dredging Co. operated a dragline dredge on the Bernhard ranch. Cinco Mineros Co. worked a dragline dredge the entire year. A dragline dredge operated by the Honcut Dredging Co. handled over 200,000 cubic yards of gravel on the Drescher property. The same company worked another dragline dredge on the Ford property. Dragline dredges were operated on Fortuna Acres and the Kehriotis property by the Butte Gold Dredging Co. The Penn Dredging Co. worked a dragline dredge from February to the end of the year on the Granella ranch. Some dragline work was done by the same company on the Ora M. Wheeler property. Richter & Sons operated a dragline dredge on Honcut Creek from March 25 to the end of the year. This company also did some dragline dredging on the Ross Lands Orchard Co. property. The Western Dredging Co. worked a dragline dredge in Wymans Ravine near Oroville from October 7 to the end of the year. By far the largest placer mine was that operated by the Yuba Consolidated Gold Fields Co., which worked an electric-power dredge of the connected-bucket type with a capacity of 9,500 cubic yards per 24 hours throughout the year.

Palmero district.—The Wyandotte Gold Dredging Co., which operated a dragline dredge on the Farnham ranch, was the leading producer in the Palmero district in 1936.

Yankee Hill district.—Hoeffling Bros. worked the Surcease mine throughout 1936 and treated a large quantity of gold ore in a 50-ton cyanide plant. Over 1,900 feet of development work were done, and an average of 39 men was employed. Several smaller operations, both lode and placer, were reported in the district.

CALAVERAS COUNTY

Camanche district.—The Atlas Gold Dredging Corporation operated a dragline dredge at the Gilhousen mine during 1936. A dredge of the connected-bucket type was operated throughout the year on Camanche Creek by the Camanche Placers, Ltd. The Comanche Gold Dredging Co. also operated a dredge of the connected-bucket type along the Mokelumne River, as did also the Lancha Plana Gold Dredging Co. A dry-land dredge of the Gold-Gravel Products, Inc., worked foothill placer ground near Wallace until May 24. The Wallace Dredging

Co. started operating its connected-bucket-type dredge on October 11 and continued operations until the end of the year.

Campo Seco district.—Drift mining at the Buffalo What Cheer and the Fourth of July properties were the most productive operations reported in the Campo Seco district in 1936.

Copperopolis district.—A number of lode and placer operations were reported in the Copperopolis district in 1936. Gold ore was mined at the Mountain King mine by the Jumbo Consolidated Mining Co. and a tailings dump was treated by the Gold Knoll Mining Co. at the Gold Knoll property.

East Belt district.—The Fine Gold Mining Co. worked the Fine Gold quartz mine throughout 1936 and treated the ore in a 40-ton ball mill by flotation. The Mar-John property was reported active the first part of the year. Old tailings were treated at the 100-ton cyanidation plant built during the year by the Union Consolidated Mining Co. at the Oro Plata mine near Murphy. A small quantity of ore from the Total Wreck property northeast of Angels Camp was treated in a 5-stamp mill. Numerous other lode and placer mines were reported active in the district.

Jenny Lind district.—The Royal mine was worked throughout 1936, and the ore was treated in a 20-stamp mill by amalgamation and flotation. A dragline dredge of the Milton Gold Dredging Co. worked gravel on Clear Creek and South Gulch.

Mother Lode district.—The section of the Mother Lode district that traverses Calaveras County has a number of productive gold mines located on it. By far the largest producer in 1936 was the Carson Hill operated by the Carson Hill Gold Mining Corporation. An average of 174 men was employed, and over 6,700 feet of development work were done. The ore was treated in a 1,000-ton amalgamation and cyanidation plant, which was enlarged during the year. The Lucky Joe Gold Mining Co. worked the Easy Bird mine. Gold ore was shipped for smelting from the Gopher Hill mine 9 miles from Milton by the Gopher Hill Mining Co. The Consolidated Mines of California treated the ore produced from the McKisson property 20 miles from Mokelumne Hill by amalgamation and flotation. The Morning Star mine, developed by open-pit method, was operated for a short time during the summer by the California Osborn Mining Co. The Mother Lode Central Mines, Inc., did 1,200 feet of development work at its property and had a small quantity of ore tested at the Russell mill near Angels Camp. The Delaray Mines developed the Gospel and Comet claims near San Andreas throughout the year and built a 100-ton amalgamation and concentration plant and other surface buildings; a small quantity of ore mined from an open-cut by power shovel was treated late in the year. The larger placer producers in the district were drift mines. The Calaveras Central Gold Mining Co. worked the Calaveras Central and produced a large quantity of gold. Another large producer was the Golden River Mining Co., which worked the Golden River property near Mokelumne Hill. The Tonopah Development Co., also a large producer of gold by drift mining, ceased operations at the Vallecito Western at the end of October, when the company lease terminated. A smaller drift operation was carried on at the Buck Bros. mine near San Andreas. A very small dredge of the connected-bucket type treated ore and hydraulic tailings in Chili Gulch. The dredge had

23 buckets of 1-cubic foot capacity each. The Flume House drift mine southwest of Mokelumne Hill employed an average of four men throughout the year.

ELDORADO COUNTY

East Belt district.—Ore from the Morey mine, which was operated throughout 1936, was treated in a 5-stamp amalgamation and concentration mill. The Cooley drift-placer mine was worked intermittently during 1936. A number of other lode and placer properties reported production.

Mother Lode district.—A very large number of lode and placer operations were reported in 1936 along that part of the Mother Lode that crosses Eldorado County. The Beebe-Alpine property was worked by the Beebe Gold Mining Co. throughout the year; the ore was treated in a 400-ton flotation and cyanidation mill. Another large lode producer was the Big Canyon mine worked by The Mountain Copper Co., Ltd.; the company employed an average of 128 men throughout the year and shipped to a smelter concentrate produced from ore treated in the 300-ton flotation mill. Over 2,700 feet of development work were driven and 3,800 feet of diamond drilling done. A substantial quantity of gold was recovered at the Black Oak mine near Garden Valley. The Briarcliffe Mines, Ltd., worked its mine until July and treated the ore produced in a 100-ton flotation mill; the concentrate was shipped for smelting. The Montezuma-Apex Mining Co. operated the Montezuma mine from the first of the year until July 13 and the Union Mine from March 1 until the close of the year. The ore from both mines was treated in the company 240-ton amalgamation and flotation mill. The Middle Fork Gold Mines Co. worked the Sliger mine and treated the ore in a 100-ton flotation mill. The Gold Co., Ltd., treated a large quantity of ore mined at the Veerkamp ranch near Garden Valley. In addition to the lode operations a large number of placer mines were worked in the Mother Lode district. The Pilot Hill Mining Co. operated a dry-land dredge on its Boulder claim (10 miles from Auburn). The Placeres De Oro Co. took over the Carpender drift mine on March 1 and operated from June 1 to the close of the year with 15 men employed. A dry-land dredge worked throughout the year near Lotus on the American River.

Rescue district.—The Gold Reserve mine was closed down during 1936 after a large tonnage of low-grade ore had been treated by cyanidation.

FRESNO COUNTY

Friant district.—There were several lode and placer operations in the Friant district in 1936. The Grant Service Rock Co., Consolidated, had the largest output of gold, which was obtained as a byproduct of its sand and gravel business.

HUMBOLDT COUNTY

Orleans district.—A large number of placer miners were active in the Orleans district during 1936. Two giants were in operation at the Pearch mine during the year.

IMPERIAL COUNTY

Cargo Muchacho district.—The Sovereign Development Co. treated the ore produced in 1936 at the Sovereign group near Ogilby at a 25-ton cyanide plant. Approximately 1,000 feet of development work was done during the year; an average of 17 men was employed. Riggs & Horgan leached old tailings at the Tumco mine in a 40-ton cyanide sand plant.

INYO COUNTY

Big Pine (Fish Springs) district.—In 1936 gold ore was treated by amalgamation at the Commetti mine by the Birch Creek Mining & Milling Co. Lessees on the Cleveland mine treated a small tonnage of ore at a custom cyanidation plant.

Carbonate district.—A small quantity of ore from the Coffin mine (37 miles from Shoshone) was treated by amalgamation in 1936.

Cerro Gordo district.—Gold ore was cyanided and lead ore shipped for smelting in 1936 from the Estelle-Cerro Gordo mine. The Keeler Gold Mines, Inc., treated gold ore by amalgamation from the Keeler mine during the early months of the year; the company prepared to handle custom ore as well. Lead ore was shipped for smelting from the Santa Rosa mine by the Santa Rosa Mines Development Co.

Chidago district.—The principal operation in the Chidago district in 1936 was the Cardinal Gold Mining Co., whose Cardinal mine was active throughout the year. The ore was treated in a 300-ton flotation plant and the concentrate shipped for smelting. The company distributed \$100,000 in dividends to stockholders during the year.

Chloride Cliff district.—A number of miners were active in the Chloride Cliff district during 1936; most of the ore produced was shipped.

Modoc district.—The Orondo mine recovered a considerable quantity of gold by drift mining in 1936.

South Park district.—The American Eagle, Buster Brown, Margaret No. 2, Oro Grande, Radcliffe, and Stockwell were the principal producing mines in the South Park district in 1936.

Wild Rose district.—A number of miners were reported active in the Wild Rose district in 1936. The Silver Ball, Tuchi, Finance, and Napoleon mines were productive during the year.

KERN COUNTY

Agua Caliente district.—Lode and placer mining was reported active, and both ore and gold tailings were treated at mills in the Agua Caliente district in 1936.

China Grade district.—In 1936 the Kern Rock Co., Ltd., recovered a substantial quantity of gold as a byproduct from its sand and gravel plant.

Cove district.—The Kern Mines, Inc., worked the Big Blue mine throughout 1936 and treated a large tonnage of ore in its 100-ton flotation mill; an average of 36 men was employed, and 550 feet of development work were driven.

Havilah district.—The Bald Eagle and Drunkard's Dream produced small quantities of lode gold in 1936.

*Mojave district.*³—The discovery by Holmes on Soledad Mountain

³Jullihn, C. E., and Horton, F. W., *The Golden Queen and Other Mines of the Mojave District, California*: Inf. Circ. 6931, Bureau of Mines, 1937, 42 pp.

in 1933 started more productive activity than any other strike in California in recent years. The ground where the discovery was made is now occupied by the Golden Queen Mining Co., the largest producer in the Mojave district and third largest silver producer in the State. This company employed an average of 145 men throughout 1936 and did over 9,800 feet of development. Ore was treated in the recently constructed 250-ton cyanide plant. The Lodestar Mining Co., a consolidation of a number of claims, including the Star Light, the Elephant, and Eagle groups, was the second largest producer on Soledad Mountain in 1936; the company employed an average of 39 men and did over 5,000 feet of development work. Most of the ore was treated by cyanidation, but some was shipped for smelting. The Soledad Extension mine of the Soledad Mojave Mining Syndicate was also an important producer in the district. This company shipped its ore to the cyanide plants operated by Burton Bros., Inc., which operated the Tropico mine and also one of the largest custom mills in the State. Both mine and custom ore was treated in a 100-ton cyanidation plant. A number of operators, including the Whitmore Mines, Inc., worked mines on Bowers Hill, and development with some production was reported from the Middle Buttes area.

Randsburg district.—The largest mine in the Randsburg district, the Yellow Aster, was operated throughout 1936 by the Anglo American Mines Corporation. This company treated a large tonnage of old tailings by cyanidation and a smaller tonnage of ore by amalgamation; an average of 78 men was employed throughout the year. The Butte Lode Mining Co. worked the Butte Lode mine during 1936 and did a small amount of custom-mill work in addition to amalgamating the ore it produced. The Buckboard mine was an important producer in the eastern part of the district. The Sunshine mine was operated during the last half of the year. In addition to the lode mines discussed, a number of other mines were in operation, most of them under lease. Placer operations were also reported in the district.

Woody district.—Several small operations, including dry-land dredging at the Horned Lark (Maltby) property, were reported in the Woody district in 1936.

LASSEN COUNTY

Hayden Hill district.—The Golden Eagle and the Juniper mines, operated by the Hayden Hill Gold Corporation, were the principal producers in the Hayden Hill district during 1936.

LOS ANGELES COUNTY

Cedar district.—The Governor Mining Co. operated the Governor mine and treated a considerable tonnage of gold ore by amalgamation in 1936. A number of smaller mines were also productive.

Neenach district.—The Suzanna and Valvue properties worked by Rogers and Gentry were the principal producing mines in the Neenach district in 1936. Over 900 feet of development work were done and a considerable quantity of gold ore was shipped for treatment at cyanide plants and smelters.

Saugus district.—The Marsam Gold Co. operated a dry-land dredge on the Conroy ranch property in Bouquet Canyon, leased from the

Soledad Placer Co., Ltd., in 1936. Early Californians discovered gold here over a 100 years ago.

San Gabriel district.—Small lode and placer operations were reported in the San Gabriel district in 1936.

Valyermo district.—A small shipment of bullion was made from the Big Horn mine late in 1936. The Allison Mining Co. worked its property (20 miles east of Azusa) throughout 1936 and treated its ore in a 25-ton ball mill by amalgamation and concentration.

MADERA COUNTY

Hildreth district.—Several lode mines in the Hildreth district, including the Red Bud, Buckeye, Keystone, Williams, and Parker, yielded small outputs of gold recovered by amalgamation in 1936.

Potter Ridge district.—Several small placer operations were reported in the Potter Ridge district in 1936. High-grade gravel was worked at the Bell mine by hand methods.

MARIPOSA COUNTY

Colorado district.—The Golden Empire Mining Co. worked the Schroeder group of mines and treated a considerable tonnage of gold ore by amalgamation in 1936; it was the largest producer in the Colorado district. Several smaller operations, including the Mocking Bird, Rex, Trabucco claims, and Twin Springs mines, were reported active.

Hite Cove district.—The Original and Ferguson mines were operated throughout 1936 by the San Juan Ramsey Co. of Boston. A large tonnage of ore was treated by amalgamation in a mill equipped with two concentrating tables. Most of the concentrate was cyanided, but a small tonnage was shipped for smelting. An average of 28 men was employed throughout the year, and over 2,300 feet of development work, including nearly 350 feet of shaft sinking, were done.

Hunter Valley district.—Old tailings at the Ruth Pierce mine (12 miles east of Merced Falls) were treated by a lessee in a 15-ton cyanide plant in 1936. Over 500 feet of development work were done and a small quantity of ore was treated at the San Gabriel mine. At the Orange Blossom property some production of gold by amalgamation was recorded, and over 250 feet of shaft-sinking and 400 feet of drifting were reported. In addition to the lode mines, Kumle and Ferris operated a dragline dredge from the middle of March until the end of the year; an average of 14 men was employed. The operators incorporated their business late in 1936 for operations in 1937 under the name of the Placer Properties Co., Inc.

Mother Lode district.—The southern end of the Mother Lode terminates in Mariposa County, and on it a number of small and medium-size mines were working during 1936. Gold ore was treated in a 5-stamp mill at the Ortega mine from April until the end of the year. Work at this property included the cleaning out of an old shaft from which Mexicans were said to have been evicted by General Fremont when he took possession of the Fremont grant in the early days. Development and some production at the Lovely Rogers mine east of Merced Falls were reported by Givens Bros. A shaft 100 feet deep was sunk at the Black Oak mine, and some ore was treated by amalgamation. The Hasloe mine was worked throughout the year, and the

ore recovered was amalgamated in a 5-stamp mill; a small tonnage of concentrate produced was not shipped. The Early Gold mine was worked intermittently, and a small output of gold was reported. In addition to the lode mines, a large number of placer miners worked the district during the year; the majority were snipers. Much of the placer gold recovered was sold through local gold buyers.

Whitlock district.—Development of Our Chance and Golden Key lode mines was reported in 1936 with an output from each being recorded. The Diltz mine was the largest producer in the district.

MERCED COUNTY

Snelling district.—Connected-bucket dredges in the Snelling district accounted for virtually all the gold produced in Merced County during 1936. The Snelling Gold Dredge Co. operated its 2 boats throughout the year and employed an average of 39 men. Each dredge had a daily capacity of 6,500 cubic yards and was electrically operated. The Yuba Consolidated Gold Fields also had two electrically operated dredges in the district, one with a capacity of 7,500 cubic yards and the other 4,500 cubic yards per 24-hour day. An average of 45 men was employed. The Merced Dredging Co. operated one electric-powered dredge with a capacity of 9,000 cubic yards per 24-hour day. In addition to these companies, the San Joaquin Mining Co. built a large connected-bucket-type dredge during the year for operations early in 1937.

MONO COUNTY

Bodie district.—The outstanding operation in Mono County during 1936 was that of the Roseklip Mines Co. at Roseklip mines, a group centering about the old Standard mine. This company built a 250-ton combination sand and slime cyanide plant and started milling on October 8. A considerable quantity of ore was treated by the end of the year. In addition, a number of lessees working on the same properties sent to the mill small quantities of old tailings and ore. The Blue Point mine was operated throughout the year and the ore produced was treated in a 15-ton stamp mill by amalgamation.

Chidago district.—A number of small operators reported the mining of gold ore in the Chidago district during 1936. The Gibson Oil Co. worked the Gold Crown mine in the Indian section. Other producers were the Gold Wedge, Beckman, Starter, Sierra Vista, New Deal, and Long Chance properties.

Topaz district.—A small quantity of lead ore was shipped to a smelter in 1936 from the Antimony property; over 200 feet of development work were done.

NEVADA COUNTY

French Corral district.—The Bradley Mining Co. worked the San Juan mine throughout 1936 and shipped gold ore for smelting. A number of small placer operations were also reported in the district. On Deer Creek a small connected-bucket dredge worked until November on the Dawson ranch (10 miles above Smartville). This dredge had 30 connected buckets, each of 1-cubic foot capacity, and was driven by gasoline power.

Grass Valley-Nevada City district.—The gold production of the Grass Valley-Nevada City district in 1936 continued to make it the leading metal-producing district of the State; in fact, this district was

among the largest in value of production in the United States. The Empire Star Mines Co., Ltd. (41.4 percent of its stock is owned by Newmont Mining Corporation), operated the Empire, Pennsylvania, North Star, Murchie, and Zeibright mines and was developing another mine named the Pennsylvania near Browns Valley, Yuba County. According to the company printed annual report, the Empire, North Star, and Pennsylvania mines at Grass Valley produced 244,473 tons with a metallurgical recovery of 95.39 percent or 0.368 fine ounce of gold per ton and an operating cost of \$8.47. At the Murchie mine in the same district 102,401 tons of gold ore were milled with an average recovery of 0.217 ounce of gold and 0.745 ounce of silver; at the Zeibright mine east of Grass Valley 129,886 tons of ore were milled.

The Idaho Maryland Mines Corporation worked the Idaho Maryland and the Brunswick properties in the Grass Valley-Nevada City district and also carried on a large operation in the Forbestown district, Butte County, described elsewhere in this report. According to the company printed annual report, 293,975 tons of ore were produced at its Grass Valley operation, which had a gross recovery value of \$3,308,450.45 or an average of \$11.25 per ton. In addition, a large quantity of old tailings were treated by the company, and an extensive custom business in the reduction of ore and concentrates was carried on by the company's metallurgical works. During the year, 34,460 linear feet of development headings were driven and 13,458 feet of diamond drilling done. One of the most unusual developments in mining in California was the sinking of a circular shaft⁴ with a 5-foot-diameter core drill, using chilled shot as the cutting medium. This shaft was sunk to a depth of 1,125 feet and placed in operation in July 1936.

The Lava Cap Gold Mining Corporation worked the Lava Cap, Banner, and Central properties and treated its ore in a 300-ton flotation concentration mill; the concentrates were shipped to a smelter. During the year 500 feet of shaft sinking and over 17,000 feet of other development work were done. An average of 229 men was employed throughout the year. At the Golden Center mine a large tonnage of ore was treated at an 80-ton stamp mill and a 125-ton flotation plant. The bulk of the gold and silver was recovered as bullion, but the gold concentrate saved by flotation yielded a considerable revenue when smelted. The company reported starting experimental work with scrapers in stopes. At the other company mine, the Kenny, two lessees produced a small quantity of gold ore. The Hoge mine of the Great Northern Gold Mines, Inc., was worked by lessees throughout the year; the ore produced was treated in a 75-ton flotation mill, and the concentrate was shipped for smelting. The Republic Gold Mining Corporation operated the Empress mine for the first 2½ months of the year and treated the ore produced in a 200-ton flotation plant. The Spring Hill Gold Mines, Inc., developed its property northeast of Grass Valley throughout the year and operated its 100-ton flotation plant from the first of the year until August 5. The company flotation concentrate was shipped to the Idaho Maryland custom cyanide plant. A number of small placer operations were reported in the district.

⁴ Newsom, J. B., and Jackson, C. F., Shaft Sinking with a Shot Drill, Idaho Maryland Mine, Grass Valley, Calif.: Inf. Circ. 6923, Bureau of Mines, 1936, 10 pp.

Washington district.—The Bradley Mining Co. worked the Spanish mine (23 miles northeast of Nevada City) throughout 1936 and treated the bulk of its production in its 100-ton flotation and cyanidation plant; the concentrate and a small quantity of gold ore were shipped to a smelter. Although the principal product of the mine was gold, a considerable revenue was derived from the silver, lead, and copper content of the ore. Several other lode operations with smaller outputs were reported in the district. The Ancho Erie was closed down early in the year. In addition, a number of placer mines were worked during the year. The Shovel Placer Co. operated the Trude property on Spring Creek with a power shovel and stationary washing plant. The Davis Flat drift mine was one of the more productive placers. Western Gold, Inc., worked the Relief Hill mine by the hydraulic method and employed an average of 13 men during the first 6 months of the year. Two giants, each under a 250-foot head of water, were used.

PLACER COUNTY

Auburn district.—A dry-land dredge operated in 1936 at the Old Montezuma mine on the Hughes ranch southeast of Lincoln, and a number of other smaller placer operations were reported. The Burm-Ball Mining Co. at the Sisley ranch and the Rising Sun Mining Corporation, both lode properties, reported development work.

Butcher ranch district.—Development work proceeded during 1936 at the Sleepy Dutchman lode mine near McKeon, where it was hoped to develop a very large body of low-grade ore.

Colfax district.—Gold ore was treated by amalgamation and concentration at the Big Oak mine in the Colfax district in 1936. An average of 13 men was employed until the mine was closed down in September.

Dairy Farm district.—Operations at the Dairy Farm mine were suspended in 1936, and the machinery was sold.

Foresthill district.—A number of small operations, both lode and placer, were reported in the Foresthill district during 1936.

Gold Run district.—There were a number of large-scale placer operations in the Gold Run district in 1936. At the Fay placer mine a dragline dredge with a washing plant having a capacity of 800 cubic yards in 16 hours worked throughout the year. The Jasper-Stacey Co. worked the Recalp Co. property with a dragline dredge. Another large dragline operation was that of the Lincoln Gold Dredging Co., which employed an average of 12 men throughout the year and treated almost 450,000 cubic yards of bench gravel. The Oakwood Placer Mining Co. operated a dragline dredge with a capacity of 1,000 cubic yards every 24 hours and employed an average of 11 men throughout the year. On the Ruben Johnson ranch a dry-land dredge was operated from the middle of March until the end of the year.

Iowa Hill district.—There were a number of operations in the Iowa Hill district in 1936, including drift mining on the Truro property north of Iowa Hill, sluicing at the property of the Campbell Gold Mines, Inc., in the Wisconsin Hill section, and hydraulicking at the Lost Camp mine near Blue Canyon.

Last Chance district.—The Capitol Glenn Mining Co. worked a drift mine in the Last Chance district for a short time in 1936. The Echoless lode mine was active the early part of the year.

Loomis district.—The Gold Hill Dredging Co. operated its dredge, of the connected-bucket type, throughout 1936 and treated over 840,000 cubic yards of river gravel. The Antelope Creek Dredging Co. worked its Antelope Creek property with a dredge of the same type. The Lincoln Gold Dredging Co. started work with its dry-land dredge in September; another dry-land washing plant using a dragline excavator worked the Miners Ravine property during the early months of the year. Drift mining was reported at the SERA and Yellow Jacket mines.

Michigan Bluff district.—Drift mining was reported at the Burn's Channel mine northeast of Michigan Bluff in 1936; testing work was carried on throughout the year.

Ophir district.—The Auburn-Pacific mine was worked by the South Star Gold Mines Co. until May 1, 1936, when it was taken over by the Auburn Pacific Mines, Inc. The latter company installed a headframe, hoist, pumps, blacksmith shop, and other equipment and produced a small quantity of gold from test runs made before the end of the year. Smaller outputs were reported at the TWA, St. Lawrence, and Two Orphans mines.

PLUMAS COUNTY

Butte Valley district.—Sluicing was carried on in 1936 at the Yankee Bar-Riverside-Marion Creek and Feather River No. 1 properties and drift mining at the Phillips Bench, Boomerang, and Glacier mines.

Crescent Mills district.—The Indian Valley Mining Co., Inc., worked the Standart mine near Greenville in 1936 and treated its ore in a 10-stamp mill. The Gold Stripe mine was worked by the Almanor Gold Mining Co. throughout the year; the ore was treated in a 50-ton amalgamation and flotation mill. A number of small placer producers were active.

Genesee district.—The Walker Mining Co., an affiliate of the Anaconda Copper Mining Co., operated the Walker mine throughout 1936 and was the principal mineral producer in Plumas County; the mine is the largest copper mine in the State and is equipped with a 1,600-ton flotation plant. According to the company's printed annual report 468,453 tons of ore were broken during the year and 453,794 tons milled, from which 21,998 tons of concentrate was produced; the total metal paid for was 9,614,277 pounds of copper, 268,141 ounces of silver, and 11,666.57 ounces of gold. The company did almost 14,000 feet of development work during the year. A small output of gold ore from the Gold Leaf mine was reported.

Lights Canyon district.—The Bill Lode mine and the Lucky S placer mine were the leading producers in 1936 in the Lights Canyon district.

Quincy district.—A number of placers were operated in the Quincy district in 1936. A dry-land dredge operated the Brilliant placer property near Twain during the summer months.

Virgilia district.—The Virgilia Mining Corporation milled a large tonnage of ore in its 125-ton flotation plant in 1936. This mill was built during the year and started operations late in August. The concentrate was shipped for smelting and was valued chiefly for its gold content.

RIVERSIDE COUNTY

Chuckawalla district.—Mining was reported at the Golden Key and Red Cloud properties during 1936.

Dale district.—The Gold Crown Mining Co., Ltd., worked the Gold Crown and Nightingale claims throughout 1936 and treated its gold ore in a 50-ton all-slime cyanide plant. One thousand feet of development work were done, including 100 feet of shaft sinking. The Mission Gold Mining Co. worked continuously developing the Huff-Lane property (50 miles northeast of Mecca) and treated a small quantity of gold ore by amalgamation in an arrastre. Development work and mining were reported at the Golden Rod and Star mines.

Pinacate district.—There was considerable activity in the Pinacate district during 1936, and several small yields of gold were reported. A small tonnage of gold ore from the Hoag mine was treated in a 10-ton 2-stamp mill.

Pinon district.—In 1936 old tailings were worked by cyanidation at the Lost Horse mine near Twentynine Palms, and a small tonnage of gold ore from the Blue Bell property was milled.

SACRAMENTO COUNTY

Consumnes district.—The Consumnes Gold Dredging Co. operated a connected-bucket-type dredge with capacity of 10,000 cubic yards per 24 hours the last quarter of 1936.

Folsom district.—The Folsom district was the most productive placer area in the State in 1936. The Natomas Co. operated 6 dredges of the connected-bucket type and employed an average of 280 men throughout the year. Two of the dredges ceased operations in April 1936, but the company had two dredges under construction at the end of the year. The Capital Dredging Co. operated 3 dredges in the district, all of which were powered by electricity; this company employed an average of 91 men throughout the year. Gold Hill Dredging Co. had one dredge working in the Folsom district and handled almost 2,000,000 cubic yards of gravel during the year. A dredge with a 5,000 cubic-yard-per-day capacity was operated by the Sacramento Gold Dredging Co. throughout the year. A dry-land dredge at Mississippi Bar was worked for a part of the year by the Camp Exploration Co., Inc.

SAN BERNARDINO COUNTY

Calico district.—Cyanidation of old tailings in the Calico district in 1936 yielded most of the gold and silver outputs. Ore from the Comanche and Sioux claims was cyanided; silver was the predominant metal in the ore.

Holcomb Valley district.—A small dry-land dredge worked the Marple claim at the head of Van Duzen Canyon the latter part of 1936. Small placer operations in the district yielded approximately 250 ounces of gold.

Ivanpah district.—A small shipment of silver ore from the Stonewall Jackson mine was sent to a smelter in 1936, and 200 feet of development work were done.

Old Woman Mountains district.—Production was reported in 1936 from the Gemco (Mable group) and Goldfield No. 1 mines.

Randsburg district.—Although the larger part of the Randsburg district lies in Kern County, an important section extends into San Bernardino County. Silver ore was shipped to a smelter in 1936 from the Santa Fe group, and over 2,500 feet of development work were done. The Coyote mine was operated during the first 3 months of the year, and gold-silver ore was shipped for smelting. In the Atolia section of the district the Atolia Rand Placers, Inc., operated a gravel-washing and concentration plant and recovered a considerable quantity of gold as well as tungsten materials.

Silver Mountain district.—Gold-silver ore was treated in a 20-ton concentration plant at the Carbonate mine during the later months of 1936, and a lead concentrate was shipped to a smelter.

SHASTA COUNTY

Clear Creek district.—The Golden State Dredging Co. operated a dragline on Olney Creek from June 4 until the end of 1936. Another dragline dredge was working in China Gulch near Redding from August 7 until the end of the year. The Lone Hill mine was worked with a stationary washing plant supplied with gravel by a gas shovel and truck. In addition, a large number of small placer miners worked the creek gravel.

Cottonwood Creek district.—The Midland Co. operated a floating washing plant and dragline shovel, both equipped with Diesel power throughout 1936.

French Gulch district.—Several lode and placer operators were active in the French Gulch district during 1936.

Igo district.—The Pioneer Dredging Co. operated two dragline dredges in the Igo district throughout 1936. On December 29, a third boat was put into operation.

Iron Mountain district.—The Mountain Copper Co., Ltd., worked the Iron Mountain property and was the largest producer of gold and silver in Shasta County in 1936; the ore was treated in a 600-ton cyanide leaching plant; an average of 84 men was employed throughout the year.

Shasta district.—The Dowling Mining & Investment Co. worked the Walker mine throughout 1936 and built a 100-ton all-slime countercurrent decantation cyanide plant, which was put into operation on August 17. A dry-land dredge treated 100,000 cubic yards of stream gravel at the Clear Creek Placers 5 miles from Shasta.

SIERRA COUNTY

Alleghany district.—The Original Sixteen to One Mine, Inc., worked the Original Sixteen to One and the Tightner mines continuously in 1936 and treated a large tonnage of gold ore in a 100-ton amalgamation and concentration plant; an average of 77 men was employed, and over 1 mile of development headings was driven. The Kenton mine north of Nevada City was worked throughout the year, and the gold ore produced was treated in the 30-ton, 10-stamp amalgamation mill there. Over 1,000 feet of development work, including the sinking of 350 feet of inclined shaft, were done during the year. Gold ore from the Ruby mine was treated in a 30-ton stamp mill with amalgamation followed by tabling and flotation. Over 7,000 feet of development were done during the year. The Oriental Mining Co. worked the Oriental mine during the last 6 months of the year and

treated the ore produced in a 10-stamp mill. Socorro Mines, Inc., worked the Plumbago mine all year. Over 1,100 feet of development work were done, and the ore produced was treated in a 10-stamp mill. In addition to the lode mining, a large number of small placer properties were worked.

Downieville district.—Virtually all the gold produced from the Downieville district in 1936 was derived from placer mines.

Gold Lake district.—A dry-land dredge worked for a few months in 1936 on the Golden Meadow mine patented claims.

Pike district.—The Scales Placer Mining Co. worked the Scales property (12 miles northeast of Strawberry Valley) by the hydraulic method in 1936.

SISKIYOU COUNTY

Klamath River district.—A number of small mine operators as well as snipers were active in the Klamath River district during 1936. The Kah Sek Co. operated a dragline dredge on the Tony Lund Bar from April 1. The Reeve mine near Happy Camp was worked by hydraulicking during the year. The Lowden mine was also worked by hydraulicking.

North Central district.—Gold ore was treated in a 12-ton, 5-stamp mill at the Mount Vernon property, which was worked continuously during 1936. The Cal Oro Dredging Co. operated a dredge with a capacity of 3,000 cubic yards per 24 hours on Greenhorn Creek. A substantial quantity of gold was recovered from the Big Boulder and Big Oak drift mine near Hawkinsville.

Salmon River district.—In 1936 the King Solomon Mines Co. treated a large tonnage of ore from the King Solomon mine in the Liberty section in its 300-ton amalgamation mill; a very extensive exploration campaign of trenching with tractors and bulldozers was carried on during the first 3 months of the year; approximately 10½ miles of trenches were opened. In addition, over 3,000 feet of underground headings were driven. A very large number of placer operations, most of them small, were reported. Gravel was hydraulicked at the Banner, S. T. S., Tea Bar, Dig More, Joubert, Summerville, and a number of other properties.

Scott River district.—There were many operations, both lode and placer, in the Scott River district in 1936. Among these, the Northern California Goldfields, Inc., worked the Morrison-Carlock mines and treated the ore produced in a 10-stamp mill. Ore was mined and amalgamated at the Fairview No. 1, Gold Reef, Mountain View, and Star mines; 30 men were employed.

TRINITY COUNTY

Big Bar district.—A number of small placer operations were reported in the Big Bar district in 1936. The M. R. K. Mining Co. worked the Osborn Hill mine by the hydraulic method until the end of April, when the lease was surrendered.

Hayfork district.—In 1936 the Hayfork Gold Dredging Co. operated a dragline dredge from September 22 to the end of the year. The plant used diesel power and had a capacity of 3,000 cubic yards per 24 hours; an average of 19 men was employed. Gold ore was produced at the Ballyhoo mine, where development work was carried on actively.

Helena district.—The Chiksan Oil Co., Ltd., worked the Enterprise mine 50 miles west of Redding throughout 1936 and operated its 10-stamp mill for 8 months. An average of 18 men was employed at the property.

Junction City district.—The Junction City Mining Co. operated an electric-powered dredge of the connected-bucket type, with a capacity of 7,000 cubic yards per 24 hours throughout 1936. The Red Hill mine of the Northern California Mines Co. was worked by independent miners under operating agreements. Lode mining was also reported in the district.

Lewiston district.—In 1936 the Trinity Dredging Co. worked continuously a dredge of the connected-bucket type, with a daily capacity of 3,000 cubic yards. The Brown Bear mine, operated by the Brown Bear Mining Co., was the largest producer of lode gold in the county during 1936. A number of small mines, both lode and placer, also were productive.

New River district.—A large number of lode and placer operations accounted for the gold output of the New River district in 1936.

Salyer district.—In 1936 the Swanson Mining Corporation hydraulicked a small quantity of bench gravel on the South Fork of the Trinity River.

Weaverville district.—The Redding Creek Placer, Inc., was the largest producer of placer gold in the Weaverville district in 1936; hydraulic operations were carried on until June 8.

TUOLUMNE COUNTY

Columbia district.—Pocket hunters continued to search the hills of this district during 1936, and a number of very rich discoveries were made. In addition to the pocket hunters, a number of miners worked placer deposits. The Springfield drift placer was operated by the Springfield Land Co. and produced a considerable quantity of gold. Sizeable outputs were reported from the Experimental and Little Bonanza lode mines.

East Belt district.—The Columbus Gold Mining Co. worked an average of 45 men at the Columbus mine near Tuolumne throughout 1936 and treated gold ore by amalgamation and flotation in a 30-ton stamp mill; 3,956 feet of development work were done. A 15-ton concentration mill treated the ore mined at the Jigger Bill's Brother mine also near Tuolumne. Development work was carried on at the Telegraph mine east of Chinese Camp and a 5-ton stamp mill was built. The Soulsby-Belle mine was operated by the Soulsby-Belle Mining Co. the full year. A number of placer operations were reported in the district, the largest of which was a dry-land dredge operated near Chinese Camp by the Menke-Hess Gravels, Inc.

Mother Lode district.—The Hitchcock mine was worked throughout 1936 and the ore produced treated in a 50-ton amalgamation and concentration mill. The Oak Mesa mine (8 miles northeast of Merced Falls) was under development during 1936 and produced a small quantity of ore that was treated in a 30-ton stamp mill. Experimental milling was carried on at the Eagle Shawmut mine preparatory to reopening in 1937.

YUBA COUNTY

Browns Valley district.—Ore was treated by amalgamation in 1936 at the Sweet Vengeance property near Browns Valley. The Empire Star Mines Co., Ltd., continued an extensive exploration campaign at its Pennsylvania mine 25 miles west of its Grass Valley mines.

Smartville district.—The Gold Exploration Mining Co. worked the Blue Point gravel mine by drift mining in 1936; an average of 30 men was employed throughout the year, and its production made the company one of the important drift operators in the State. On the Yuba River near Smartville was one of the largest camps of gold "snipers" in California; even at low water probably 100 miners were working the river gravels at various times.

Strawberry Valley district.—A number of small placer operations using hand methods were reported in the Strawberry Valley district in 1936.

Yuba River district.—By far the largest operation in 1936 in Yuba County was that of the Yuba Consolidated Gold Fields, which had a fleet of five large gold dredges of the connected-bucket type working throughout the year in the Yuba River district.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO

(MINE REPORT)

The total output of gold, silver, copper, lead, and zinc from Colorado ore and gravels in 1936, in terms of recovered and estimated recoverable metals, was 366,607.00 fine ounces of gold, 5,902,776 fine ounces of silver, 17,730,000 pounds of copper, 14,534,000 pounds of lead, and 2,344,000 pounds of zinc. This output compares with a production in 1935 of 349,280.80 ounces of gold, 4,696,064 ounces of silver, 14,654,000 pounds of copper, 11,345,000 pounds of lead, and 2,403,000 pounds of zinc. There were 714 lode mines and 601 placers producing in 1936, a decrease of 156 lode mines and 241 placers from 1935. The smaller number of lode mines in 1936 than in 1935 is due to a decrease in the number of mines, prospects, and dumps producing less than 25 tons of ore, each of which is counted in this report as a producing mine if the material sold yielded any recovered metal. The decrease in the number of placers is explained by the fact that fewer individuals were engaged in sluicing and panning than in 1935; also one floating dredge that was operated in 1935 was idle in 1936.

The total recorded output from Colorado ores and gravels from 1858 to 1936, inclusive, all in terms of recovered metals, has been, according to Chas. W. Henderson, 36,446,165 ounces of gold, 678,-248,882 ounces of silver, 374,148,430 pounds of copper, 4,650,756,583 pounds of lead, and 2,239,203,985 pounds of zinc.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the

table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932-36

Year	Gold	Silver	Copper	Lead	Zinc
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>

¹ Dragline and power-shovel excavators with sluices or special amalgamators.

² Figures for sluicing and hydraulic include those for dry-land dredges.

³ Figures for sluicing and hydraulic include those for drift mining.

Gold.—The production of gold in Colorado in 1936, in terms of recovered metal, was 366,607.00 fine ounces valued at \$12,831,245, an increase of 17,326.20 ounces in quantity and \$606,417 in value over 1935. In 1936 the Cripple Creek district contributed 141,608.20 ounces (38.63 percent of the State total). Park County yielded 56,267.20 ounces (15.35 percent); Boulder, 25,963.20 ounces (7.08 percent); Clear Creek, 24,441.60 ounces (6.67 percent); Gilpin, 22,569.80 ounces (6.16 percent); San Juan, 22,162.00 ounces (6.05 percent); Lake, 15,284.80 ounces (4.17 percent); Rio Grande, 12,989.14 ounces (3.54 percent); San Miguel, 12,231.60 ounces (3.34 percent); Eagle, 11,947.00 ounces (3.26 percent); and Ouray, 8,979.20 ounces (2.45 percent). The largest increases were 17,284.20 ounces in Teller County, 8,070.60 ounces in Clear Creek, 6,034.00 ounces in San Juan, and 4,870.14 ounces in Rio Grande; the largest decreases were 15,675.66 ounces in Park County and 4,516.94 ounces in Jefferson. Dry and siliceous ores yielded 91.52 percent of the total gold, copper and copper-lead ores 2.89 percent, lead and lead-zinc ores 1.89 percent, and placers 3.70 percent.

Silver.—The production of silver in Colorado in 1936, in terms of recovered metal, was 5,902,776 fine ounces valued at \$4,571,700, an increase of 1,206,712 ounces in quantity and \$1,196,404 in value over 1935 compared with an increase of 1,220,403 ounces in quantity and \$1,128,404 in value in 1935 over 1934. In 1936 Eagle County produced 3,697,632 ounces (62.64 percent of the State total); San Juan, 432,603 ounces (7.33 percent); Mineral, 422,071 ounces (7.15 percent); Ouray, 406,244 ounces (6.88 percent); and Pitkin, 198,319 ounces (3.36 percent). The largest increases were 905,362 ounces in Eagle County, 180,061 ounces in Ouray, and 150,185 ounces in San Juan; the only important decreases were 77,609 ounces in Mineral County and 51,009 ounces in Dolores. Dry and siliceous ores yielded 32.98 percent of the total silver, copper and copper-lead ores 62.84 percent, lead and lead-zinc ores 4.14 percent, and placers 0.04 percent.

Copper.—The production of recoverable copper in Colorado in 1936 was 17,730,000 pounds valued at \$1,631,160, an increase of 3,076,000 pounds in quantity and \$414,878 in value over 1935. Eagle County produced 15,932,700 pounds (90 percent of the State total); next in order were San Juan (991,400 pounds), Ouray (250,500 pounds), and Clear Creek (187,400 pounds). The largest increases were 2,749,700 pounds in Eagle County, 367,400 pounds in San Juan, and 57,400 pounds in Clear Creek; the largest decrease was 67,000

pounds in Park County. Copper ore yielded 90 percent of the total copper, dry and siliceous ores 9 percent, and other types of ore 1 percent.

Lead.—The production of recoverable lead in Colorado in 1936, reckoned as lead in lead bullion and in leaded zinc oxide, was 14,534,000 pounds valued at \$668,564, an increase of 3,189,000 pounds in quantity and \$214,764 in value over 1935. In 1936 Lake, Ouray, Park, San Juan, and San Miguel Counties each produced more than 1,000,000 pounds. The other important producing counties were Eagle, 982,800 pounds; Pitkin, 669,000 pounds; and Clear Creek, 578,300 pounds. Dry and siliceous ores yielded 54 percent of the total lead; lead ore, 31 percent; copper and copper-lead ores, 9 percent; and lead-zinc ore, 6 percent.

Zinc.—The zinc-bearing ores and concentrates marketed from Colorado in 1936 contained 2,344,000 pounds of recoverable zinc valued at \$117,200, a decrease of 59,000 pounds in quantity from 1935, but an increase of \$11,468 in value due to the higher average price in 1936. Lead-zinc sulphide ore shipped from Lake County to the pigment plant at Coffeyville, Kans., and zinc-lead ore containing gold, silver, and copper shipped from Dolores, Gunnison, Lake, and Summit Counties to reduction plants in Utah contained most of the zinc recovered from ore mined in Colorado in 1936; the remainder was produced from zinc concentrates (a byproduct of dry silver ore from Pitkin County and dry gold ore from Gilpin County) shipped to Amarillo, Tex.

MINE PRODUCTION BY COUNTIES

² Figures for sluicing and hydraulic include those for drift mining.

MINING INDUSTRY

The bulk of the ore produced in Colorado, 1933-36, was dry and siliceous gold, gold-silver, and silver ores and copper ore valuable chiefly for its gold and silver content. The output of these ores totaled 2,115,175 tons, or 98.3 percent, of the State total for all classes of ore in 1936; 1,744,691 tons, or 98.5 percent, in 1935; 1,299,469 tons, or 99.3 percent, in 1934; and 832,873 tons, or 98.5 percent, in 1933. The increase of 151 percent in output of dry and siliceous ore in 1936 over 1933 resulted principally from large expenditures of capital for consolidating, developing, and equipping old gold- and silver-producing properties. Large-scale mining and milling of lead and lead-zinc ores, suspended in 1930-31, had not been resumed to May 20, 1937. In 1929 combined lead and lead-zinc ores constituted 42 percent of the State total for all classes of ore. The quantity of gravel handled in 1936 at placer mines by 1 floating bucket-type dredge and 23 land-dredge installations was approximately 943,478 yards; specific data on yardage handled at small-scale placer operations are not obtainable because of lack of knowledge by the operator of the quantity of gravel sluiced.

To continue annual detailed statistics for Colorado on mine production by classes of ore, methods of recovery of metals, and mining districts, the data for 1935 not available for inclusion in Minerals Yearbook, 1936, are supplied in this chapter.

ORE CLASSIFICATION

Ore sold or treated in Colorado, 1935-36, with content in terms of recovered metals

Source	Ore	Gold	Silver	Copper	Lead	Zinc

METALLURGIC INDUSTRY

There were large successive increases in Colorado in 1935 and 1936 over 1934 in the quantity of combined gold and gold-silver ores treated by flotation concentration. Concentrates produced from these ores yielded a large part of the State lead output in both years. Equipment for the recovery of gold and silver in ore and concentrates by cyanidation was provided at seven mills in 1936 compared with four in 1935 and three in 1934. Details of cyanidation, flotation, and other plants operating in 1936 are given under the following district reviews.

Custom ore-reduction plants operating in Colorado in 1936 were: The lead bullion-lead copper matte smelter at Leadville; Golden Cycle roast-amalgamation-cyanidation-flotation mill at Colorado Springs; Boulder Mill at Salina, Lehman mill at Jamestown (short period only), and St. Joe sampling plant at Boulder, Boulder County; Humboldt Consolidated (formerly Clear Creek-Gilpin) sampler and mill, Ruth, and Gold Center mills at Idaho Springs, Dumont mill at Dumont, and Watrous mill at Silver Plume, Clear Creek County; War Dance mill, Gilpin County; Bryant mill, Lake County; Alma Milling & Metals Corporation mill, Park County; Shenandoah-Dives mill, San Juan County; Wilfley mill at Kokomo, Summit County; and Cripple Creek mill, Teller County.

Ores were shipped to custom plants in other States in 1936 as follows: Zinc-lead sulphide ore from Lake County to Coffeyville, Kans.; zinc concentrates from Pitkin and Gilpin Counties to Amarillo, Tex.; iron-copper-silver-gold ore from Eagle County, copper-gold-silver concentrates from Clear Creek County, gold-silver-lead-[zinc] ore from Chaffee County, and gold and gold-silver-lead ores and concentrates from the San Juan region to Utah smelters; and zinc-lead-silver-gold ore from Dolores, Gunnison, Lake, and Summit Counties to selective flotation mills at Midvale and Tooele, Utah.

Details of treatment of the total ore produced in Colorado in 1935 and 1936 are shown in the following tables.

Mine production of metals in Colorado, 1935-36, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
1935			<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>

Ore and concentrates treated by amalgamation, ore, concentrates, sands, and slimes treated by cyanidation, and gold and silver contained in bullion and precipitates in Colorado, 1935-36

Process	Material treated	Gold in bullion	Silver in bullion	Quicksilver purchased	Sodium cyanide used
1935	<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>
Amalgamation.....	866, 891	53, 610. 69	21, 082	2, 765	
Cyanidation.....	¹ 558, 476	122, 850. 90	56, 218		² 474, 021
1936					
Amalgamation.....	865, 905	63, 804. 72	17, 596	2, 077	
Cyanidation.....	³ 686, 908	133, 580. 70	48, 573		⁴ 647, 385

¹ Includes 364,037 tons of sands and slimes from ore and concentrates known to have been first roasted and amalgamated, 169,087 tons of estimated tailings from ore first floated and other sands and slimes from iron concentrates first amalgamated, and 25,352 tons of crude ore cyanided.

² Reduced to equivalent of 96- to 98-percent strength. Actually 914,818 pounds of cyanamid of approximately 48- to 49-percent strength and 16,612 pounds of sodium cyanide of 96- to 98-percent strength.

³ Includes 386,710 tons of sands and slimes from ore and concentrates first roasted and amalgamated, 202,019 tons of tailings from ore first floated, 6,064 tons of flotation iron concentrates and 35,363 tons of crude ore first roasted, and 2,437 tons of flotation and table concentrates and 54,315 tons of crude ore cyanided direct.

⁴ Reduced to equivalent of 96- to 98-percent strength. Actually 1,065,690 pounds of cyanamid of approximately 48- to 49-percent strength and 114,540 pounds of sodium cyanide of 96- to 98-percent strength.

Mine production of metals from gold and silver mills in Colorado, 1935-36, by counties, in terms of recovered metals

Includes Granite, Lackawanna Gulch, St. Kevin, Tennessee Pass, and Twin Lakes districts.

The Granite district lies in both Chaffee and Lake Counties.

ADAMS COUNTY

Individuals working intermittently with sluices and small placer machines along Clear Creek and South Platte River produced most of the output of gold from Adams County in 1936. The remainder was recovered during January, February, and March by temporary sluice boxes placed below waste flumes of the Gordon sand and gravel plant.

ARAPAHOE COUNTY

The output from Arapahoe County in 1936 comprised gold dust and amalgam retorts produced by individuals at small placers on Cherry and Dry Creeks and their tributaries southeast of Denver. All the output was sold in small lots to bullion buyers in Denver.

BOULDER COUNTY

In 1936 the principal markets for Boulder County ores and concentrates were the Golden Cycle mill at Colorado Springs and the A. V. smelter at Leadville. At its sampler at Boulder, the St. Joe Mining & Milling Co.² purchased ore, mostly in less-than-carload lots, and reshipped it to the Golden Cycle mill. At Salina the Boulder Mill, Inc., concentrated ores from mines in the various districts of Boulder County in its 100-ton flotation mill, at a specified charge per ton, until near the end of the year when the company began to purchase ores. Seven miles southeast of Boulder near Marshall the Capitol Refining Co. erected a custom ore-reduction plant designed to treat high-grade gold ores and concentrates. Test runs on several lots of concentrates in August and September proved unsuccessful, and the plant was closed. In December the Colorado Smelting & Refining Co. of Denver took over the plant and by May 30, 1937, had removed part of the equipment and enlarged the building to make room for a roasting furnace (Herreshoff type), additional ball mills, flotation cells, tables, and other equipment with which the company plans to start a 100-ton roast-amalgamation-flotation custom plant in August or September 1937.

Central district (Jamestown).—The Wano group produced the bulk of the output of metals from the Jamestown district in 1936. Part of the ore was mined and shipped by lessees to the Golden Cycle mill at Colorado Springs, and part was mined on company account and either shipped to the Golden Cycle mill or, if too low in grade for direct shipment, was concentrated in the company flotation mill; the concentrates were shipped, some to the Leadville smelter and some to the Golden Cycle mill. Other producers in the Jamestown district included the Acme, Cracker Jack, Eureka, Fourth of July, Gold Finch, Golden Age group, Gray Eagle, John Jay, Last Chance, McKinley, and Smuggler. The Lehman mill at Jamestown was operated for a short period on ore from the Grouse mine. Erection of the 40-ton mill of the Acme Mining & Milling Co., designed to treat ore from the John Jay mine, was completed in 1936, but the mill was not placed in operation.

Gold Hill district.—The Slide Mines, Inc., continued in 1936 to mine and mill ore from its properties opened by the Corning Tunnel. The ore is treated in the gravity- and flotation-concentration mill at

² Mining and milling operations of the St. Joe Mining & Milling Co. are mentioned in the district reviews.

the mouth of the tunnel. Additions to the mill in 1936 included a washing and sorting plant and steam-heating equipment. The capacity of the mill at the end of 1936 was 70 tons daily. The United Empire Gold Mines Co. operated the 125-ton flotation mill, built at its property at Sunshine in 1935, at less than full capacity for 341 days in 1936, chiefly on dump ore and old stope fillings. At the Ingram mine the Mines Development Corporation unwatered the lower levels, extended the southwest drift on the 710-foot level 170 feet, and deepened the shaft 100 feet. Custom ore treated at the Boulder Mill from mines in the Gold Hill district came largely from the Ingram, Big Horn, Minneapolis, Fairfax, Emancipation, and Grant, listed in order of tonnage milled. Part of the ore produced from several of these mines was shipped to the Golden Cycle mill. Some of the other producing mines in the Gold Hill district in 1936 were the Baron group (Garfield Charles), Buena Ventura, Evans, Evening Star, Golden Harp, Goldsmith Maid, Nil Desperandum, Plow Boy, Prussian, Richmond group, Scotia, Sunshine, Seven-Thirty, Tippecanoe, Washburn, and Winona. A small sluicing operation on Left Hand Creek yielded a little placer gold.

Grand Island district (Cardinal, Caribou, Eldora, and Nederland).—The Rocky Mountain Gold Mines, Inc., operated its 100-ton flotation mill at Cardinal at less than capacity on ore from the Boulder County group from March 1 to August 1, 1936, when the company suspended operations. The product of the mill was gold-silver-lead concentrates, which were shipped to the A. V. smelter at Leadville. From June through December the Cross Gold Mining Co. drove 389 feet of drifts and raises at the Cross group and shipped a few cars of ore. Other producing mines in the Grand Island district in 1936 were the Amy Paul, Enterprise group, St. Louis, Sweet Home, and Stranger. Small lots of ore were shipped from two prospects in the district. Placer gold was recovered by individuals sluicing on Beaver Creek.

Magnolia district.—Most of the metal output from the Magnolia district in 1936 was contained in crude ore shipped to the Golden Cycle mill, a large part of which came from dumps. The principal producing mines and dumps were: American X, Ben C. Lowell, Cash, Graphic, Hereafter, India, KeKeonga, Keystone, Lady Franklin, Little Pittsburg, Mary V, New Year-Fortune, Pickwick, Poorman, and Senator Hill.

Sugar Loaf district.—The Grand Republic mine of the St. Joe Mining & Milling Co. was operated continuously in 1936 and was again the largest producer of gold in Boulder County. The inclined shaft begun in 1934 had been sunk to a depth of 280 feet by the end of 1936, with working levels established at 50, 100, 160, 220, and 280 feet. Development done in 1936 totaled 3,320 feet. The ore was trucked to the St. Joe 100-ton flotation mill on Left Hand Creek (Gold Hill district) for treatment until October 1 when the company closed that mill, due to the difficulty and expense of maintaining tailing dams, and moved the equipment to a new plant completed and placed in operation late in November at Valmont near Boulder. Ore mined between October 1 and the time the new mill was completed was shipped to the Golden Cycle mill. Lessees at the Poorman mine continued to ship ore to the Golden Cycle mill and the sampler at Boulder. Ore from the Nancy, Livingston, and Logan groups was shipped to the Golden Cycle mill, Boulder Mill, and Boulder Sampling Works. Other important producers in the Sugarloaf district were the

Concord, Dolly Varden, Empress, Herold, Milan, Recluse, Red Signe, Smoky Hill, Wisconsin, Wood Mountain, and Yellow Pine. Most of the placer gold recovered in the district came from a power shovel and movable washing and amalgamating plant operated at the Colby-Giggey placers.

Ward district.—The Golden Queen mine in Left Hand Gulch 1 mile from Ward, operated continuously, was the principal producer of metals in the Ward district in 1936. The ore was shipped to the Garfield (Utah) smelter and the Golden Cycle mill. The other output from the district comprised gold ore shipped from the Chief claim, East Columbia, Milwaukee, Nelson, Richard, Stoughton, and Ward Rose; silver ore from the Black Jack claim; and miscellaneous small lots of ore, mostly samples shipped from prospects.

CHAFFEE COUNTY

Chalk Creek district (Romley, St. Elmo).—In 1936 lessees at the Mary Murphy mine continued to produce most of the output of metals from Chaffee County from gold-silver-lead-copper-[zinc] ore shipped to custom mills or smelters for treatment. The Philip Carey Mining & Milling Co. unwatered the Lilly winze and Quincy shaft and shipped one lot of silver ore to the Leadville smelter. Several lots of silver-lead ore were shipped from the Allie Bell group, and one lot of silver-lead-gold ore was shipped from another property in the district, all to the Leadville smelter.

Four Mile district.—Lessees operated the Little Annie C. C. group most of 1936 and shipped several lots of gold ore to the Leadville smelter.

Granite district.—Operators of lode mines in the Granite district in 1936 shipped small lots of smelting ore from the Florence Extension, Trafalgar, and other properties. The H. & H. Mining Co. shipped a car of gold ore from the Granite Tunnel to the Golden Cycle mill. Placer gold was recovered from the Bugtown, Cache Creek, Franklin, Georgia Bar, Old Channel, and other placers near Granite.

Riverside district.—Continuing operations begun in 1935 at the Mount Harvard group, the Williams Mining Co. shipped three cars of gold-silver-lead-[zinc]-copper ore to the Leadville smelter in 1936. In July the company closed the mine and gave up its lease. Two lots of gold ore shipped from the Big Chief property and a car of gold-silver-lead ore shipped from the Blue Flag comprised the other output from the Riverside district in 1936.

Trout Creek district.—Lessees operated the Dolomite group from January 1 to August 28, 1936, during which time they retimbered 100 feet of shaft, sank a 100-foot winze, drove 340 feet of tunnel, and did 50 feet of trenching on the surface. They produced and shipped 8 tons of silver ore. A small lot of ore was shipped from the Nelly Bly prospect. Diamond drilling was done at the Iron Chest group 1 mile west of Trout Creek Pass on Trout Creek.

Turret district.—Emil Becker shipped one lot of gold ore from the Monongahela claim to the Golden Cycle mill early in 1936 and during the year drove 167 feet of tunnel at the property. A small lot of gold ore was shipped from a prospect in the Turret district.

CLEAR CREEK COUNTY

Alice district (Yankee, Lincoln).—The Alice property was the chief producer in the Alice district in 1936. Reopened in 1935 by the Porphyry Mines, Inc., and equipped with an 80-ton amalgamation-flotation concentration mill, the mine was operated by that company until March 4, 1936, when the American Smelting & Refining Co. took it over and proceeded to carry out a program of mine development and surface improvements. Parts of the mine-development program completed in 1936 included a 225-foot inclined main shaft, a 125-foot inclined prospecting shaft, and about 700 feet of drifts and raises. Slushing replaced mucking and tramming in the mine. Surface improvements completed included the installation of new crushing equipment, ore-conveyor belts, ore bins, and enlargement of the mill to raise its capacity from 80 to 200 tons per 24 hours. The ore is crushed by a 15- by 38-inch Telsmith-Wheeling jaw crusher and is ground by a No. 66 Marcy ball mill in closed circuit with a Dorr classifier and a Clark-Todd amalgamator. The overflow from the classifier is conditioned and treated by selective flotation (copper over iron) in a 6-cell and a 4-cell sub-"A" flotation machine. The products of the mill are gold-copper-silver-[iron] concentrates which are shipped to the company smelters at Garfield, Utah, and Leadville, Colo., and gold-silver bullion which is shipped to the Denver Mint.

Small stamp-amalgamation mills were used in 1936 to treat ore from the Lalla and Reynolds mines, and some ore was shipped from the Lombard and Ottawa groups and the Ethel prospect.

Argentine district.—The 50-ton flotation mill built in 1935 at the Santiago mine was operated for 100 days in 1936, from June to September, and treated about 3,500 tons of ore from the Santiago dump. Gold-silver-copper concentrates produced at this mill and 66 tons of crude ore from the Santiago mine and Blue Bell group yielded the total output of metals from the Argentine district in 1936.

Empire district.—The Minnesota Mines, Inc., operated its Crown Prince-Atlantic-Comet consolidated group of mines and 100-ton cyanide plant continuously in 1936 and was the largest producer of gold in Clear Creek County. The ore was treated by the all-sliming cyanide process, but late in the year the company began to install flotation equipment with which to concentrate the ore before cyanidation and increase the capacity of the mill to 200 tons daily. Mine timbering at the Conqueror group was repaired, and the 50-ton flotation-gravity concentration mill was reconditioned and operated for a short period in the last part of the year. Other producing mines and dumps in the Empire district were the Bard Creek, Cashier, Gold Bug, Gold Dirt, Gold Fissure, Mint, Pittsburg, and Tenth Legion.

Geneva Creek district.—The output from the Geneva Creek district in 1936 comprised gold-silver ore shipped from the dump of the Sill property to the A. V. smelter at Leadville.

Griffith (Georgetown-Silver Plume) district.—The Watrous 65-ton custom flotation mill near Silver Plume was run for short periods in 1936 on ore from the Rio Grande-Zeda mine and from the Blue Bell group (Argentine district). Ore was shipped to the Leadville smelter and local custom mills from the Amy, Backbone, Capital Prize, Commonwealth Tunnel, Griffith, and Odin properties and three prospects.

Idaho Springs district.—The Alma Lincoln Mining Co. was the leading producer of metals in the Idaho Springs district in 1936. The ore

came from the Lincoln (lower levels) and Elliott-Barber mines and was treated in the company 100-ton flotation mill. The new 60-ton flotation mill of the Consolidated Smelting & Metals Co. on Chicago Creek treated 12,000 tons of ore from the Black Eagle and Bismark mines, connected with the mill by a 3,300-foot aerial tramway. The sampling works and 75-ton flotation-concentration mill formerly operated by the Clear Creek Gilpin Co. were acquired early in 1936 by the Humboldt Consolidated Mining Co., which discontinued the buying of ores and concentrates about March 15, 1936, and used the mill thereafter chiefly for treating company ores from its Lord Byron group. The Mattie amalgamation-flotation and gravity-concentration mill was operated at the rate of about 20 tons a day during most of the year on ore from the Mattie group. The 25-ton flotation-concentration custom mill of the Ruth Co. at Idaho Springs treated ores from various mines in the district on the basis of a specified charge per ton. The 150-ton flotation mill built at the Bruce mine in 1935 was operated during January, February, and part of March 1936, but not at full capacity. The Gold Center mill at Idaho Springs was run part of the year on ore from the American Girl mine in Gilpin County. Other producing mines included the Belgian Hare, Bride, Cardigan, Castleton, Dixie No. 4, Dona Juanita-Maud Monroe, East Lake (dump), Gem, Kangaroo, Kitty Clyde, Lincoln (upper levels), North American group, Old Settler, P. T., Red Jacket, Shafter, Stephens Placer (Big Chief tunnel), Three Brothers, Two Brothers, and Victor.

Montana district (Lawson, Dumont).—Producers of a car or more of ore in the Montana district in 1936 were the American Sisters (dump), DeCapriva (Climax), and Murray properties. Smaller lots were shipped from the Central American, Gold Trust, Hopeville, and Red Elephant. The Dumont mill was used by C. B. Myers to treat miscellaneous lots of custom ore from January to May, when the flotation-concentration section was leased to the Phoenix Trail Mining Co. and was operated continuously from August 8 to the end of the year on ore trucked from the Phoenix mine in the Trail Creek district.

Trail Creek district.—The substantial gain in production of gold in the Trail Creek district in 1936 over 1935 was due largely to increased output from the Phoenix mine, operated continuously throughout 1936. Lessees at the Freeland group continued mining on a small scale; most of the ore produced was treated in the 45-ton flotation-gravity concentration mill at the mouth of the drainage tunnel near Dumont. Ore was shipped to the Leadville smelter, Golden Cycle mill, and Ruth mill from the Donaldson (Wheatland)-Little Champion group, Great Western, Lone Tree, and Turner mines, and a 1-ton lot of ore was sold to the sampler from a prospect in the district.

COSTILLA COUNTY

Grayback district.—Sluicing operations at the Last Chance No. 3, Drum Estate placer, and one other placer in Grayback Gulch yielded 13.20 fine ounces of gold in 1936.

CUSTER COUNTY

Hardscrabble district (Westcliffe, Silver Cliff).—Ore was shipped to the Leadville smelter from the Deceiver, Kline, and Passiflora mines and two prospects in the Hardscrabble district in 1936. Lessees

shipped 230 tons of ore from the Nemaha and William dump to the Golden Cycle mill.

Rosita Hills district.—The output from the Rosita Hills district in 1936 was 191 tons of gold-silver ore shipped to the Golden Cycle mill from the Bassick and Margaret-Mary dumps and 111 tons of lead-silver ore shipped to the Leadville smelter from other properties.

DOLORES COUNTY

Lone Cone district (Dunton).—No production of metals has been recorded from the Lone Cone district since 1930, but in 1936 the Modern Gold Mines, Inc., cleaned out and retimbered mine workings and erected a 120-ton flotation mill at the old Emma mine, a former producer of gold-silver ore. Testing of the mill on stope fillings was begun in December.

Pioneer district (Rico).—Ore produced from mines in the Pioneer district in 1936 was zinc-lead-copper-silver-gold ore, and all was sold to custom milling plants or smelters at Midvale and Tooele, Utah. Producers were the Mines Leasing Syndicate from the Burns mine, Hicks Lease on the Rico Townsite, and the Pro Patria group of the Rico Enterprise Mining Co.

DOUGLAS COUNTY

Miscellaneous sluicing and panning operations in Newlin and Lemon Gulches and on Cherry Creek near Parker and Franktown yielded small lots of placer gold in 1936. The Cook Mining Co. reported development work at its lode prospect 1 mile north of Palmer Lake.

EAGLE COUNTY

Burns and McCoy district.—Prospectors recovered small lots of placer gold in 1936 by panning and sluicing at a placer on the Colorado River 5 miles west of McCoy.

Red Cliff district (Battle Mountain).—The Eagle mine group of the Empire Zinc Co. (New Jersey Zinc Co.) was the largest producer of silver and copper in Colorado in 1936, as for several preceding years, and was an important producer of gold from copper-iron-silver-gold sulphide ore shipped to smelters at Garfield and Murray, Utah. The company 600-ton flotation mill, built underground in Eagle Canyon below Gilman in 1929 and operated on ore from zinc-lead ore bodies of the Eagle mine group to December 1, 1931, remained idle in 1936. Other producers, principally of gold ore shipped to smelters or the Golden Cycle mill from ore bodies in the Cambrian quartzite formation on Battle Mountain, included the Alpine, Ben Butler, Black Tiger, Ground Hog, Pine Martin, Star of the West, Tiptop, and Zang, or Emma Tunnel group.

EL PASO COUNTY

GOLDEN CYCLE MILL

Operating continuously in 1936, the Golden Cycle custom mill at Colorado Springs treated 494,566 tons of gold-[silver]-sulphotelluride ores from the Cripple Creek district and 47,443 tons of miscellaneous gold and gold-silver ores and concentrates, mostly from Boulder, Clear

Creek, Gilpin, Lake, and Park Counties, with occasional lots from other districts in Colorado, New Mexico, South Dakota, and Wyoming. The plant includes a sampling mill, secondary crushing unit, 450-ton flotation mill, 1,200-ton roasting section, fine grinding-amalgamation³-classification section, sand and slime cyanide plant, and precipitation and refining department. Ores purchased vary in character and grade and therefore are not all treated by the same methods. Gold ores of average grade, comprising principally Cripple Creek ores, are roasted, amalgamated, and cyanided. Low-grade Cripple Creek ores and nearly all miscellaneous ores are concentrated. Iron concentrates produced are mixed with the average grade gold ores and travel with them through the roasting and other processes. The tailings from the flotation mill are cyanided. Some of the miscellaneous ores contain appreciable quantities of copper, lead, and zinc in addition to gold and silver. These are treated by selective flotation, yielding lead-copper-gold-silver-[zinc] concentrates which are shipped to the Leadville smelter.

FREMONT COUNTY

The Webb flotation-concentration mill was completed at the Florence dump of the Bee Zee Metallic Corporation early in 1936 and was operated for several months during the year. As this dump is composed of tailings from mills that treated Cripple Creek ores, the metals recovered are included in the production of Teller County. A prospector sluicing on the Arkansas River recovered a little placer gold.

GILPIN COUNTY

Southern districts (Black Hawk, Central City, Nevada, Russell Gulch).—The largest producer of metals (chiefly gold) in Gilpin County in 1936 was the United Gilpin Corporation, which treated by amalgamation and table concentration 287,058 tons of low-grade gold ore from its consolidated group of mines. Most of the ore was mined by the glory-hole system at "The Patch" property on Quartz Hill and was transported 3,250 feet from the mouth of the La Cross tunnel to the mill at Central City by aerial tramway. Ore treated from other company properties was trucked to the mill. The company suspended large-scale milling operations in February 1937, stating that it was unable to find a solution of the problem of tailings disposal that was satisfactory to the farmers of Clear Creek Valley.

At Blackhawk the Gregory-Bates Mining Co. reopened the Bobtail Tunnel, which yielded part of the ore treated at the company mill in 1936. The ore is crushed with stamps, passed over carpet-lined launders, and concentrated on Wilfley tables. The carpet concentrates are amalgamated and the table concentrates are reground in a ball mill and cyanided. The company-leased holdings as of April 3, 1937, comprised the Gregory, Bobtail, Fisk, Cook, and Mammouth (formerly the "Fifty" gold mines group), and Packard Mammouth; the company owns the Mammouth 366a and the Mammouth 371. The company leases on the Hunter-Bates, Becker-Bates, Gaston, Hartford, and O'Neil mines were given up. The 275-ton Pittsburg mill of the Russell Gulch Mining Co. treated 28,375 tons of mine and dump ore by gravity concentration from January to May. The War Dance 10-stamp mill between Central City and Blackhawk was

³ Free gold saved on lightweight canton flannel blankets and amalgamated in iron arrastre.

operated most of the year on company and custom ores. The Colorado Silver Mines, Inc., erected a 100-ton flotation mill near the portal of the Black Jack shaft, which connects with the Wheeler tunnel level at a depth of about 300 feet. Operation of the mill early in 1937 on ore from the Wheeler vein was planned. Ore mined by the company in 1936 was concentrated at the War Dance mill. The Willis Gulch Mining Co. operated its 50-ton flotation mill intermittently on ore from the Anchor mine and Saratoga dump. Gold-silver-lead ore from the American Girl mine on the Queen Mineral ranch was trucked to Idaho Springs (Clear Creek County) and treated by flotation concentration in the Gold Center mill. The Gilpin Eureka Consolidated Mines, Inc., made test runs of its 65-ton selective flotation mill in November and produced 61 tons of lead concentrates and 17 tons of zinc concentrates; the latter were shipped to the zinc smelter at Amarillo, Tex. Mine and dump ore was shipped to custom plants outside the county, chiefly to the Golden Cycle mill and A. V. smelter, from the Atlantic, Champion, Columbus, Corydon-Adeline, Druid, Egyptian, Federal, Frontenac, Golden Dollar, Incidental, Justice, Morning Star, Old Town, Pewabic group, St. Louis No. 2, Troublesome, War Dance, West Notoway, and others.

Operating its traction dry-land dredge on North Clear Creek from April 1 to November 19, the Humphreys Gold Corporation handled 612,144 cubic yards of gravel and was the second largest producer of gold in Gilpin County in 1936. The company, however, moved the equipment out of the county after the final clean-up for the year and does not plan to resume work in Gilpin County in 1937. About 6,000 cubic yards of gravel were handled by a lessee at the Eugene Placers at Blackhawk, operating a dragline and portable screening and washing plant from September 26 to December 4. Lessees at the Missions Mines Co. property in lower Russell Gulch operated a gasoline shovel and sluices intermittently and handled approximately 1,000 yards of gravel. Individuals using sluices and rockers at miscellaneous small placers in the southern districts of Gilpin County recovered 270 ounces of gold in 1936.

Northern districts.—The Gilpin County Gold Mining Corporation completed and placed in operation a 35-ton stamp amalgamation-flotation concentration-mill begun in 1935 at the We Got Em and Cowboy group at the head of Silver Creek. The mill treated 3,840 tons of ore in 1936. From August through December the Dirigo Mining Co. shipped ore to the Golden Cycle mill from its property 7 miles north of Blackhawk. Lessees at the Perigo group treated a few hundred tons of ore from the Gold Dirt dump and War Eagle claim in a small stamp mill. Operating the Newport mine after May 2, C. H. Reser drove 340 feet of drifts and winzes and treated some ore in the 10-stamp mill at the property. Small lots of ore were shipped in 1936 from the Reform, Golden Flint, and other properties in the northern districts of Gilpin County. F. H. Wolfe operated equipment comprising a gasoline power shovel and trommel screen on wheels powered by gasoline motors at placer ground in Lump Gulch during May and June and handled 4,000 cubic yards of gravel. Hydraulic mining was done at another placer in Lump Gulch, and scattered small sluicing operations yielded a little gold.

GRAND COUNTY

Placer miners sluicing intermittently on Broncho Creek and Colorado River near Granby and on a tributary of Red Dirt Creek northwest of Kremmling recovered small lots of placer gold in 1936.

GUNNISON COUNTY

Elk Mountain district.—Scattered lots of smelting ore were shipped from mines and prospects in the Elk Mountain district in 1936. Individuals recovered a little gold by sluicing at the Nora Nos. 1 and 2 and another small placer in the district.

Gold Brick district (Ohio).—The Carter mine on Gold Creek was operated continuously and yielded most of the gold produced in Gunnison County in 1936. The ore also contains comparatively small quantities of silver and lead and is treated by amalgamation and flotation- and gravity-concentration in the company mill at the portal of the 8,800-foot adit by which the mine is opened. A 16-ton lot of gold-silver-lead ore was shipped from the Raymond mine to the Midvale (Utah) smelter, and gold was recovered from ore treated by amalgamation in small mills at the Mountain Boy-Golden Wedge and Wayne properties and at a prospect near Ohio.

Taylor Park (Tin Cup) district.—Prospectors and other individuals sluicing and panning at miscellaneous placers in Taylor Park in the summer of 1936 recovered small lots of placer gold.

HINSDALE COUNTY

From January 1 to May 31, 1936, the Gallic-Vulcan Mining Corporation drove 300 feet of development drifts and raises at its property 10 miles west of Lake City. The company reported on March 20, 1937, that it was preparing to place a 50-ton flotation mill on the property. A lessee at the Gladiator property drove 50 feet of tunnel in 1936 and completed installation of a ball mill and flotation machine having a capacity to treat 15 tons of ore daily. The Golden Wonder mine was operated on a small scale.

JEFFERSON COUNTY

Individual sluicing operations along Clear Creek in Jefferson County in 1936 yielded placer gold, the greater part of which was sold in lots of less than 2 ounces to assayers and refiners in Denver; the remainder was sold to the Denver Mint. The traction dry-land dredge of the Humphreys Gold Corporation, which from 1933 to 1935, inclusive, recovered the bulk of the gold and silver produced in Jefferson County, was moved to Gilpin County in November 1935.

LAKE COUNTY

LEADVILLE DISTRICT

One furnace of the A. V. lead bullion-lead copper matte smelter of the American Smelting & Refining Co. was operated continuously as a lead-bullion plant with subsidiary lead-copper matte plant throughout 1936, and a second lead furnace was operated during January and again from August 19 to the end of the year. Receipts of ore and concentrates, all from Colorado mines, totaled 120,776 tons, an increase of 21 percent over 1935.

Most of the ore produced at underground mining operations in the Leadville district in 1936 was smelted direct at the A. V. smelter. However, the quantity of ore that was shipped from dumps far exceeded the quantity that was newly mined. The largest individual production of gold and silver was made from low-grade ore from the Ibex dump shipped to the 400-ton flotation concentration-cyanidation mill of the Leadville Metals Milling Co. for treatment. The mill was operated in each month except February and March; during the last 4 months of the year approximately 11,000 tons per month were treated. About 12 percent of the gold and silver was recovered in bullion and the remainder in concentrates, which contained considerable lead and some copper (shipped to the A. V. smelter). Gold-silver-lead ore mined from the Resurrection-Golden Contact group through the Yak Tunnel by the Zenda Leadville Mining Co. was concentrated as custom ore in the Bryant mill near the portal of the Yak Tunnel. Some of the gold-silver ores of the district were shipped to the Golden Cycle mill at Colorado Springs for treatment, and specimen gold and placer dust and retorts were sold to the Denver Mint. Zinc-lead sulphide ore from the Tucson dump and Yak Tunnel property was shipped to the pigment plant at Coffeyville, Kans., and zinc-lead-gold-silver ore from various properties was sent to the United States Smelting, Refining & Mining Co. custom concentrator at Midvale, Utah. Other principal producing mines and dumps in 1936 were the Adelaide, Belle Placer, Breece, Chippewa, Dolly B, Fanny Rawlins, Fortune, Garbutt, Highland, Ibex group (mine), Lilian, New Monarch, Ollie Reed, St. Louis, Togo, Tribune, Triumph, Valley, and Venir.

The only important producer from placers in the Leadville district in 1936 was the Pan-Due Placer Co., which operated its dry-land dredge at the Starr and American Smelting & Refining Co. placer ground in California Gulch from May 1 to December 2 and handled 140,000 cubic yards of gravel. The apparatus consists of a gasoline power shovel, screening and washing plant, and four Ainalay bowls. Small sluicing operations by individuals in the district yielded some gold.

OTHER DISTRICTS

Granite district.—Operating the Belle of Granite mine under lease from May to December 1936, the Del Oro Mines did 300 feet of development work in the mine and installed mill equipment comprising a crusher, ball mill, amalgamation plates, 4-cell flotation machine, and Wilfley table. About 100 tons of ore were treated in 1936, but the company removed the equipment early in 1937. Placer gold was produced in 1936 at small placers on the Arkansas River in the Lake County part of the Granite district.

Lackawanna Gulch district.—The only output from the Lackawanna Gulch district in 1936 was gold ore shipped from the Eureka mine to the Golden Cycle mill.

St. Kevin-Sugar Loaf district.—Gold-silver ore from the Amity and Dinero mines and gold-silver-lead ore from the Fanchon Placer were shipped to the Leadville smelter. The other output from the district in 1936 was made by the Kokem Brothers Lease.

Tenmile (Climax, Fremont Pass) district.—The Climax Molybdenum Co. mill at Climax on Fremont Pass, 13 miles north of Leadville,

operating at the beginning of 1936 at an average of 4,000 tons a day, increased the daily average to 7,700 tons before the end of the year; the daily average for 365 days was 5,466 tons. Molybdenum sulphide concentrates containing 15,216,806 pounds of elemental molybdenum were produced.

Molybdenum production at the Climax mill in Colorado, 1924-36

	Elemental molybdenum (pounds)		Elemental molybdenum (pounds)
1924 (idle first 7 months; operated last 5 months) ¹	156, 935	1931	2, 644, 399
1925	821, 757	1932	1, 913, 395

1929	3, 529, 295	1936	15, 216, 806
1930	3, 083, 000		

¹ Idle from April 1919 to Aug. 1, 1924.

Tennessee Pass district.—The output from the Tennessee Pass district in 1936 was 30 tons of gold ore shipped from the Jennie June mine.

Twin Lakes district.—The 20-ton amalgamation-gravity concentration mill built by the lessee of the Columbia claim was operated for a short period in 1936. Placer gold was recovered by lessees at the Zaitz and other placers in the Twin Lakes district.

LA PLATA COUNTY

The American Smelting & Refining Co. lead bullion-lead copper matte smelter at Durango, which was closed November 30, 1930, remained idle in 1936.

California (or La Plata) district (Hesperus, La Plata).—The May Day Milling Co. continued production from the May Day mine in 1936; the ore was treated by flotation concentration in the 50-ton mill at the mine. The Gold King group was operated most of 1936 by the trustee in charge. Near the end of the year the property was leased by the Fawn Mining Co., a Canadian corporation. The mine is equipped with a 50-ton mill, which is connected with it by an aerial tramway 8,000 feet long. In 1936 the Pioneer Gold Producers, Inc., purchased a site for a proposed custom mill near the Idaho and May Day mines and did some preliminary clearing of ground and construction work late in the year. A pilot mill at the Idaho group was run intermittently and recovered a small quantity of gold and silver. Small lots of high-grade gold ore were shipped from the Bessie G. property, Betty Jean, Cason, Last Chance, Last Dollar, Lucky Discovery-Lucky Moon-Old Comfort, Stony Creek, and Valley View.

Vallecito district.—A 6-ton lot of gold ore was shipped to the Leadville smelter from the Grizzly King group in 1936.

LARIMER COUNTY

The Little Mary Mason mine in the Masonville district was operated intermittently in 1936. The mine produced gold ore; a hand-sorted high-grade product was shipped to the Golden Cycle mill at Colorado Springs. A small lot of gold-silver ore was shipped from the Dixie claim.

MESA COUNTY

The Missouri Girl Mining Co. shipped 14 tons of copper ore from a property in the Sinbad district to the Garfield (Utah) smelter in 1936. A few ounces of gold were recovered by individuals sluicing along the Gunnison and Colorado Rivers.

MINERAL COUNTY

Creede district.—Shipments of ore to the Leadville smelter from silver mines of the Creede district were continued in 1936, but the output of silver was 15.5 percent less than in 1935. An experimental reduction mill erected to treat ore from the Commodore mine by flotation and cyanidation was operated for a short period and then closed. Producing mines in 1936 were the Amethyst, Commodore, Corsair, Del Monte-Last Chance-New York-Pittsburg group, Eunice, Manitoba-Ontario, Ochre, and Wedge.

MOFFAT COUNTY

Fourmile (or Timberlake) district.—Most of the output of metals from Moffat County in 1936 was gold recovered at placer ground comprising 880 acres about 29 miles north of Craig in secs. 2 and 11, Tps. 9 and 10 N., R. 92 W., sixth principal meridian. The property was worked spasmodically when water was available during May and June by the Gooly Placer Mines (partnership), using a tractor and "tumblebug" scraper to move gravel to sluices. The company then sold the property to the Eldorado Gold Placer Mines, which moved in a gasoline-powered dragline excavator and dry-land dredge. This equipment was operated intermittently from October 1 to November 25. The total gravel handled by the two companies was 9,546 yards. A little gold was recovered by sluicing at the Amazon, Grubstake, Old Faithful, and other small placers in the district.

Lay district.—Small-scale placer operations on Lay Creek north of Lay yielded placer gold in 1936.

MONTEZUMA COUNTY

The output of metals from Montezuma County in 1936 was derived from high-grade gold ore shipped to smelters from the Red Arrow and Outwest mines, adjoining properties in the East Mancos River area, from specimen gold sold to the mint from the Red Arrow, and from a small lot of high-grade gold ore shipped to the Golden Cycle mill from the South Point claim. The Red Arrow mine, discovered in 1933, has attracted much attention because of its yield of nuggets and specimen gold. The Outwest property (formerly called the Omaha Placers) has been prospected since 1935, and a vein yielding high-grade ore similar to that found in the Red Arrow was reported struck in January 1936. The Hesperus Mining Co. did no mining or development at the Doyle group in Rush Basin after the snow slide destroyed its mill February 15, 1936, but plans to resume work June 15, 1937.

MONTROSE COUNTY

La Sal district.—Sluicing operations on Dolores River yielded placer gold in 1936.

Paradox Valley district.—The United States Vanadium Co., which for several years has been purchasing, locating, and developing vanadium properties in the western part of Montrose County, in the old carnotite area distinguished broadly as the Paradox Valley, started one roasting and leaching unit October 15 and another December 1, 1936. This company extracts its own salt in the vicinity. It has built many new roads in the area and a new town called Uravan.

Naturita district.—Miscellaneous small placers along San Miguel River were worked by individuals in 1936, but only 76.40 ounces of gold were recovered compared with 178.49 ounces in 1935.

OURAY COUNTY

Red Mountain district.—The San Juan Metals Corporation shipped in 1936 to the Shenandoah-Dives mill near Silverton 350 tons of gold-silver-copper-lead-[zinc] ore produced during development work at the Treasury Tunnel group. The mine was operated throughout 1936, and 988 feet of development drifts and raises were driven. G. A. Franz did 824 feet of development work at the Laura Dunmore group from March 1 to December 31 and mined 400 tons of ore, which was stored in bins and chutes ready to mill.

Sneffels district.—Interruption of operations of the King Lease, Inc., by the snow slide in February 1936 that destroyed the company mill caused a decrease in output at the Camp Bird mine in 1936 compared with 1935. The mine was shut down from February 24 to March 5 and from May 16 to July 1; the mill was closed from February 24 to May 22. In rebuilding the mill the company did not change its established method of treating the ore, namely, by amalgamation on plates followed by flotation concentration. Except during the shutdown, the mill treated a daily average of 77 tons of ore in 1936. Gold-silver bullion recovered was shipped to the Denver Mint. The concentrates produced were classed as lead-copper with the principal value in gold, but they carried 24.87 ounces of silver for each ounce of gold, and also considerable zinc; the zinc was not saved at the Leadville smelter.

In 1936 Earl A. Alexander reduced and amalgamated by hand 500 pounds of high-grade ore mined from shallow workings of the Governor group and shipped 2 tons of ore to the Leadville smelter. He treated 100 tons from the Trust Ruby dump nearby in the small mill at the Trust Ruby mine, erected in 1934 with salvaged equipment consisting of 10 stamps, 2 amalgamating plates, and a Wilfley table, all run by water supplied by a 600-foot water line. Carrying on development work at the Revenue Tunnel property from January 1 to September 14 the Revenue Development Corporation drove 1,417 feet of tunnel, drifts, and raises.

Uncompahgre district.—G. A. Franz operated his 100-ton selective flotation mill 2 miles north of Ouray at a daily average of 75 tons for 257 days in 1936 on dry silver ore, which he mined through the Syracuse tunnel from his Pony Express-Upper Bachelor group and from the Lower Bachelor group which he operated for the Bachelor Development Co. Silver-lead concentrates shipped to the Leadville smelter from this mill yielded the second largest individual output of silver in Colorado in 1936, considerable lead, and some copper and gold. The McCullough lease operated the American Nettie group, Wanakah group, Jonathan claim, and O & N group as a unit continuously on a

small scale. Gold-silver ore containing some lead and copper was shipped to the Leadville smelter, and gold recovered in a small washing plant at the Wanakah was sold to the mint. A small lot of silver-lead ore was shipped to the Midvale (Utah) smelter from a prospect in the district. Some gold and silver were recovered by the Lucky Irish Mining & Milling Co. while experimenting with the operation of a placer north of Ouray with a dragline and Wilfley tables, and by a prospector sluicing on Uncompahgre River.

PARK COUNTY

Alma Placers district.—Lessees on the Alma Placers recovered approximately two-thirds of the total placer output of Park County in 1936. The larger part of the gold was recovered by operators who sank inclined or vertical shafts to bedrock and drifted, using mechanical equipment to bring the gravel to sluices on the surface.

Beaver Creek district.—A steam shovel and movable washing plant operating on Beaver Creek produced the bulk of the output of metals from the Beaver Creek district in 1936. The remainder was recovered by hydraulicking at the Shelton placer and sluicing at other placers along Beaver Creek.

Buckskin district.—Only 136 tons of ore were shipped from the Buckskin district in 1936, most of which came from the Paris group, Phillips, Red Lion, and Wyandotte-Apex group. Considerable prospecting and development work was done at these and other properties in the district.

Consolidated Montgomery district.—Several cars of gold-silver ore from the Magnolia mine and one car from the Columbia were shipped to the Golden Cycle mill in 1936. A second car from the Columbia and one lot of lead-silver ore from another property were shipped to the Leadville smelter.

Fairplay district.—Placer gold was produced in 1936 by lessees hydraulicking, drift mining, and sluicing at placer ground formerly the property of the South Park Dredging Co. on South Platte River near Fairplay.

Horseshoe district.—No ore was shipped from the Horseshoe district in 1936, but on October 19 the Barcoe Mining Co. let a contract to drive a 2,000-foot exploration tunnel at its property on Sheep Mountain comprising 9 patented claims and 42 unpatented claims in secs. 4, 9, and 10, T. 10 S., R. 78 W., sixth principal meridian. As of March 1, 1937, the tunnel, 5 feet wide by 8 feet high, had been driven 905 feet.

Mosquito district.—The Mosquito district ranked second among Colorado districts in production of gold in each year from 1931 to 1936, inclusive, except in 1932 when it ranked first. Nearly all the output came from ore bodies in the London Fault area on and adjoining London Mountain. Associated with the gold in the ores are appreciable quantities of silver and lead and some copper and zinc; none of the zinc is saved at the Leadville smelter, where most of the district ores and concentrates are sold. In 1936 the largest producers, in order, were: The London Gold Mines Co., operating the South London and London Extension groups, equipped with a 175-ton flotation mill (equipment added in 1936 to raise the capacity, formerly 125 tons); the Fairplay Gold Mines, Inc., operating the "North London" mine and 100-ton flotation mill; the London-Butte Gold Mines Co., which in March placed in operation a new 100-ton flota-

tion mill at its Butte group; W. A. Ellis, Inc., mining and shipping high-grade ore from the American mine; and lessees on the West London mine, who shipped their ore to the smelter.

East of the London Fault area the principal producer was the Hock Hocking mine, yielding silver-lead-gold ore; most of the ore was shipped crude to the Leadville smelter, but after October some was treated in the 50-ton custom mill erected close by during the year by the Alma Milling & Metals Corporation. Some ore was shipped from the Ophir group and Susquehanna claim. A small mill was completed late in 1936 at the Dauser mine, from which several lots of ore had previously been shipped to the Golden Cycle mill at Colorado Springs and the Leadville smelter. Small lots of ore were shipped from other mines and prospects in the Mosquito district in 1936. The Newbonnet Mining Co. carried on development work at the Mascotte Tunnel property. A swinging sluice box driven by an automobile engine was used to recover gold at the Pennsylvania Mountain placer, and small sluicing operations at other placers in the Mosquito district yielded a little gold.

Tarryall district.—The Peerless Mining Co. operated its equipment, comprising a power shovel, trommel screen, four Ainlay bowls, and stacker, on the Wilson placer 7 miles southeast of Como from May 18 to October 24 and recovered most of the metals produced in the Tarryall district in 1936. Individuals sluicing on Tarryall Creek recovered small lots of placer gold. Testing of old river channels by pits and Keystone drills was continued in November and December at the Peabody placer and Foster Cline ranch on Tarryall Creek, under a Class "B" loan of the R. F. C.

PITKIN COUNTY

Avalanche district.—From August 1 to December 15, 1936, lessees operated the Ground Hog-Double Decker-Gypsum group and shipped 8 tons of lead-gold-silver ore to the Leadville smelter.

Roaring Fork district (Aspen).—Operating its 50-ton flotation mill at the portal of the Midnight tunnel the Midnight Mining Co. in 1936 treated 5,000 tons of siliceous silver ore, containing some lead and zinc, extracted from the mine and 3,000 tons taken from the dump at the old Midnight shaft. The bulk of the silver was recovered in lead concentrates sold to the Leadville smelter. Byproduct zinc concentrates containing some silver and lead were produced in the zinc unit and shipped to the zinc smelter at Amarillo, Tex.

Management of the consolidated group of properties leased in 1934 by the Colorado-Duluth Mining Co., comprising the Smuggler Leasing Co. (Durant group), Della S Consolidated Mines Co. group, Percy La Salle Mining & Power Co., and Spar Consolidated Mines Co. groups, reverted to the "Aspen Leases" in April 1936; the former company made application to be dissolved as of April 30. Sublessees on the properties in 1936 shipped 18,692 tons of silver ore containing lead and lime; the lime also was paid for at the Leadville smelter.

RIO GRANDE COUNTY

Summitville district.—The Summitville Consolidated Mines, Inc., operated its Little Annie group of mines and flotation concentration-cyanidation mill continuously in 1936. Although the rated capacity

of the mill at the end of 1936 was 120 tons, the mill treated a daily average of 135 tons for 365 days in the year. The ore is brought by trucks and tramway to the mill, where it is crushed and fed to ball mills in closed circuit with a unit cell, tables, and Dorr classifier. The overflow from the classifier—65 percent minus 200-mesh—goes to Fahrenwald sub-"A" flotation cells. Tailings from the flotation machines are cyanided. Precipitation is by the Merrill-Crowe process. Concentrates produced are shipped to smelters. A small stamp-amalgamation unit was installed in 1936 to treat high-grade ore. Early in 1937 press reports stated that the company purchased the Aztec claim adjoining the Little Annie group and ended an apex suit that had been instituted against it in August 1936 by the owners of the Aztec.

ROUTT COUNTY

Hahns Peak district.—One lot of lead-silver-gold-[zinc] ore was shipped to the Midvale (Utah) smelter from the Elkhorn mine north of Columbine, which was being investigated by the Elkhorn Gold & Silver Mining Corporation in 1936. Sluicing operations at placers in Ways Gulch south of Grouse Mountain and on the north slope of Hahns Peak yielded some gold.

SAGUACHE COUNTY

Crestone district.—The Luis Maria Baca Mining & Development Co., lessee on a group of mines in the mineral section of Baca Grant No. 4, did approximately 1,000 feet of development work in the mine in 1936 and produced 3,657 tons of gold ore, which was treated in the company 35-ton flotation-concentration mill on Cottonwood Creek, half a mile from the mine and 6 miles south of Crestone. Free gold caught on carpets placed ahead of the flotation machine was amalgamated and sold to the mint, and concentrates produced were sold to the Leadville smelter. A 1-ton lot of ore was shipped from a prospect in the district.

Kerber Creek district (Bonanza).—Lessees on the Rawley mine shipped 892 tons of silver-lead-copper ore to smelters in 1936. Similar ore was shipped from the Jupiter and Whale claims, both small producers in 1936, and one lot of lead-silver ore was shipped from the Baltimore claim.

Music district.—Development work was done at the Golden Treasure group for 4 weeks in July and August 1936, and a small shipment of gold-silver-lead-copper ore was made to the Leadville smelter.

SAN JUAN COUNTY

Animas district.—The Shenandoah-Dives Mining Co. operated its 600-ton selective flotation mill near Silverton continuously in 1936. The larger part of the mill feed was gold-silver ore containing copper and lead from the company-owned and company-operated Mayflower group, which is connected with the mill by a 1½-mile aerial tram suspended across the Animas River Valley high over the Animas River. From the beginning of its operations in 1928 through 1934 the company treated only ore from its own properties, but in 1935 it began to accept custom ores from a few neighboring mines for concentration, and in 1936 the company installed sampling equipment and offered its milling facilities to a larger number of operators. Mines supplying

most of the custom ores, in order, were: Pride of the West, North Star-Sultan, Green Mountain, Vertex, Little Fannie-Philadelphia group, Treasury Tunnel (Ouray County), Coming Wonder, and King. Besides carrying on its mining and milling operations, the Shenandoah-Dives Mining Co. contracted with the American Smelting & Refining Co. to drive a 3,000-foot crosscut from the main haulage adit of the Shenandoah-Dives property to the Silver Lake group, owned by the American Smelting & Refining Co.

At the Old Hundred property, the Old Hundred Gold Mining Co. in January, February, and March, 1936, drove 700 feet of drifts and raises and constructed a 1,500-foot aerial tramway from the mine to the mill in Cunningham Gulch. Other work done included repairing the mill building, installing a new crusher, and providing facilities for tailing disposal. The mill was operated 60 days and treated 5,590 tons of ore taken out in development operations. The mine was closed March 22, 1936. Other producers in the Animas district included the Champion group, Bill Young, Mabel, Peerless, and Queen City. A little placer gold was recovered by sluicing at the Iron Magnet mill site.

Eureka district.—Producing mines in the Eureka district in 1936 were the Brooklyn group, operated continuously, and the Robert Bonner group, operated from July 15 to November 15. The Sunnyside mine, which was equipped with a 1,000-ton selective flotation mill and was an important producer of gold, silver, copper, lead, and zinc before it was shut down on September 30, 1930, remained idle in 1936.

Ice Lake Basin district.—Two lessees working at the Bandora group from May 25 to November 15, 1936, shipped 137 tons of gold-silver-lead ore to the Leadville smelter.

SAN MIGUEL COUNTY

Iron Springs district (Ophir).—Only small tonnages of ore mined in 1936 were shipped to smelters from the Iron Springs district; but due to increased metal prices late in 1936 a sizable tonnage of low-grade middlings, containing chiefly silver and lead but also some gold and copper and formerly stacked at the old Carbonero mill, was shipped to smelters in Colorado and Utah. At the Butterfly-Terrible group 285 feet of development work were done in the mine, and one lot of ore was shipped to the Leadville smelter. The mill was repaired and made ready for operation, which is planned for 1937. Other producers in 1936 included the Carribeau, Gold Bar, Montezuma, New Dominion, and Silver Bell.

Lower San Miguel district (Sawpit, Vanadium).—A few lots of gold-silver-lead ore were shipped to smelters from the Lizzie and J. L. lode properties in 1936, and some gold was recovered at small placers along the San Miguel River and its tributaries.

Mount Wilson district.—The Polar and Silver Pick mines were operated on a small scale during part of 1936, and each yielded small lots of high-grade gold ore, all of which was sold to smelters.

Upper San Miguel district.—The Smuggler Union group was operated continuously in 1936 and again yielded the bulk of the output of gold, silver, and lead from San Miguel County. The ore was treated by amalgamation followed by gravity and flotation concentration in the 300-ton mill connected with the mine by a 3,000-foot aerial tram-

way. On December 15, the Veta Mines, Inc., acquired operating control of the property and proposes to explore geologically selected zones extending to the sedimentary formations approximately 700 feet below the present workings. The San Juan Metals Corporation, in its fourth season of operating its 400-ton flotation-gravity concentration mill on old tailings 1 mile east of Telluride, was active from May 12 to October 20, inclusive, and treated 22,405 tons yielding gold-silver-lead copper concentrates which were shipped to the Leadville (Colo.) and Garfield (Utah) smelters. The 50-ton amalgamation-gravity concentration mill erected in 1935 at the Mammoth group was crushed by a snow slide in February 1936 and was not rebuilt during the year. Construction work on a 150-ton flotation-concentration mill at the Alta-St. Louis group was begun in the latter part of 1936. A clean-up at the site of the old Alta mill that burned down yielded 35 tons of gold-silver-lead ore which was shipped to the Leadville smelter. Other producers in the Upper San Miguel district in 1936 included the Cimarron dump, Grace, Lucky Strike (small milling operation on old tailings), Laura (equipped with a 15-ton amalgamation-gravity concentration mill), Royal, and Savage. Sluicing along the San Miguel River below Telluride yielded small lots of placer gold.

SUMMIT COUNTY

Breckenridge district.—The Continental Dredging Co. operated its electrically driven floating dredge on Blue River intermittently for 238 days in 1936 and handled 622,400 yards of gravel. The dredge has a capacity of 4,000 cubic yards per 24 hours and is equipped with 88 buckets, each of 7½-cubic-feet capacity. The Tiger Placers Co. dredge at Breckenridge was idle throughout 1936. A power shovel, trommel screen, and sluices were operated from May 20 to August 10 at the Bemrose-Bostwick placer in Hoosier Gulch, and similar equipment was used by Miller & Nelson in French Gulch. Hydraulic mining and drift mining at placers on French Gulch and sluicing operations on Blue and Swan Rivers, Georgia Gulch, and Farncomb Hill yielded gold.

Zinc-lead ore was shipped in 1936 from the Royal Tiger property to the custom concentrator of the United States Smelting, Refining & Mining Co. at Midvale, Utah. A 50-ton gravity-concentration mill equipped with a 4- by 4-foot ball mill, a rag table, a two-compartment Hartz jig, and three No. 6 Wilfley tables was built 5 miles east of Breckenridge to treat ore from the Carbonate mine, from which a 3,000-foot aerial tramway was constructed to transport the ore from the mine to the mill. The mill was operated for only 7 days in 1936, when snow and cold weather closed the mine. Ore was shipped to the Leadville smelter from the Arctic, Bemrose-Bostwick (producer from both lode and placer operations), Blue Flag, Blue Jay, Briar Rose, Dunkin, Fredonia, Jumbo, Mountain Mary-Frigidare, Ohio, and two other properties.

Montezuma district.—In 1936 ore was shipped from the Bullion, Burke group, Florado-Sts. John group, and Silver King mine to the Leadville smelter. The Florado Mining Co. shipped a car of zinc-lead ore to the custom concentrator at Midvale, Utah.

Ten Mile (Kokomo, Robinson) district.—Producing mines in the Ten Mile district in 1936 were the Connors Bonanza, Delaware, Gold Crest, Kokomo, and Payrock. The Wilfley mill at Kokomo was

operated for a short period on ore from the Delaware. The ore shipped from the Payrock was concentrated in the Bryant custom mill near Leadville. A portable screening and washing plant fed by a Diesel power shovel was installed late in 1936 at the McNulty placer on McNulty Gulch where the gulch enters the Ten Mile River Valley. The plant was operated for a short period before the season closed, but the gold recovered was not sold in 1936.

Wilkinson district.—Two prospectors placering in the Wilkinson district recovered a little gold in 1936.

TELLER COUNTY

CRIPPLE CREEK DISTRICT

The output of the Cripple Creek district in 1936 was 607,690 tons of mine and dump siliceous sulphotelluride gold ore yielding, in recovered metals, 141,456.46 fine ounces of gold and 16,541 fine ounces of silver, compared with 460,448 tons yielding 124,287.66 ounces of gold and 13,287 ounces of silver in 1935. In addition, placer dust and specimen gold originating in the district and sold to assayers, refiners, and the mint in 1936 by operators, specimen collectors, and others aggregated 151.74 fine ounces.

The Golden Cycle mill at Colorado Springs (operations described under El Paso County) purchased 494,566 tons (81.4 percent) of the district output of ore in 1936. The mill is owned and operated by the Golden Cycle Corporation, which also owns several mines in the district and the Midland Terminal Ry., which transports virtually all the ore received at the mill from the Cripple Creek district. Treatment rates in effect in 1935 at the Golden Cycle mill were given in Minerals Yearbook, 1936 (pp. 271–272). The same rates for treating the ore were continued in 1936, but in October the company, seeking to improve the grade of ore offered, instituted a new system for gold payments, under which it raised the price paid for gold in ore carrying a high gold content and lowered it for ore carrying 0.18 ounce of gold and under per ton.

The Cripple Creek Milling Co. purchased under contract all the ore produced from mines and dumps owned by the Stratton-Cripple Creek Mining & Development Co. (Stratton Estate) for treatment in its 500-ton flotation-roast-cyanidation mill on Globe Hill. The company also purchased on open schedule part of the production of various independent operators in the district. Operated at reduced capacity throughout 1936, the mill treated 92,424 tons of ore. In January 1937 it was shut down and up to the time this report was written (May 25, 1937) was still idle.

MINES REVIEW

The total number of producing mines, dumps, and prospects in the Cripple Creek district in 1936 was 122, including each of several separately operated mines under one general management. Production was made from mined ore at 91 mines and prospects. The three largest producing companies, in order of metal output, were the United Gold Mines Co., an operating and holding company for property scattered throughout the Cripple Creek district; the Cresson Consolidated Gold Mining & Milling Co.; and the Golden Cycle Corporation-Ajax Operations (formerly the Granite group).

The annual report of the United Gold Mines Co. for the 10 months ended October 31, 1936 (dated Dec. 20, 1936), contains the following report of the mine superintendent.

Axtel.—L. W. Reiter of Denver, who has a lease on the Axtel, is working through the Solomon shaft and is preparing to sink the shaft, starting January 1, 1937. He expects to sink an additional 100 feet. One set of split-check sublessees is operating and making a small production of low-grade ore.

Both the Fairview and Londonderry have been idle during the entire year.

The Patti Rosa has been extensively developed during the past year by the Tennessee Mines, Inc., and they have discovered a large body of medium-grade ore, and they are making a production of about one railroad carload per day. They haven't yet determined the length and width of the ore shoot.

Bonanza.—The Bonanza is under lease to the Golden Cycle Corporation, and this company has driven a crosscut to the Bonanza vein and drifted on the vein for a distance of about 100 feet. An ore shoot of very good grade about 30 feet long has been opened, and no doubt when this is developed it will be a source of production for the year 1937.

Coriolanus.—Very little work was done on this property during 1936.

Deadwood.—The Deadwood and Trachyte are being operated by the Gold Bullion Mines, Inc. This company has conducted an active campaign of development and has opened many ore shoots which will make the property very productive during the coming year.

Fendley and Shurtloff.—The larger part of these properties is under lease to the Golden Conqueror Mines, Inc., and they have recently discovered a new ore shoot on the 10th level of the Burns shaft on Shurtloff ground. The vein is in virgin ground, is of medium-grade ore, and has been opened for a distance of about 100 feet. As the ore is wider than the drift, the width has not yet been determined, but a cut-out has been started, and after chutes have been built the walls will be prospected to determine the width. Both breasts of the drift contain good ore.

This is one of the most important developments of the year on the United Gold Mines Co.'s properties.

Hardwood.—Stocklacey and associates are operating on the north end of this property and have made a small production of low-grade ore.

Hull City.—The lease of the Hidalgo Gold Mines, Inc., was purchased by the United Gold Mines Co., and the property is now being operated on company account.

May B.—No work of any consequence was done on this property during the year.

Portland.—The result of operations for the year 1936 on the Portland group has been fairly satisfactory. The group includes the Last Dollar, Portland No. 1 and 2 shafts, operated by the company with the lessees working on split check, and the Independence, Colorado City, Portland No. 3, Ocean Wave, and a number of shallow shafts and surface workings which are leased to independent lessees.

The production from dumps for the first 5 months of the year averaged about one railroad car a day, but has steadily decreased since then until at present it is about 10 cars a month.

Operations at the Portland No. 1 and Last Dollar shafts have shown a substantial operating gain during the year, and Portland No. 2 operations have shown a small operating gain.

The lessees working the outlying properties have produced a considerable tonnage of ore, some of which has been of excellent grade. Portland No. 3, operated by Community Gold Group No. 1, Inc., has produced a number of shipments which ran between 1.00 and 2.00 ounces per ton. The Colorado City shaft, operated by Colorado Gold, Inc., produced a steady tonnage of medium grade throughout the year. The Independence, under lease to Newstrom & Co., in the year ended November 1, 1936, produced a total of 138 carloads of ore with a gross value of \$23,439. A number of shallow workings, both through shafts and in open-cuts, have produced some fairly good ore as well as a fair tonnage of low-grade ore. The royalties from these operations add to the income of the company.

At the Last Dollar, an excellent grade of ore has been obtained from workings on the Hawkeye flat vein, some shipments having settled at a value of better than 4.00 ounces, or over \$120 per ton. A large tonnage from the syenite vein stopes was shipped from the 500- and 600-foot levels of the same mine. The average value of this last ore is between \$6.00 and \$7.00, but it is cheaply mined and can be handled at a small profit.

The profitable production at Portland No. 1 came from ore developed on the Diamond and Independence veins on the 400- and 500-foot levels and from the

"breccia vein" and Bobtail vein on the 600-foot level. All of the above ore was of excellent grade. It is interesting to note that all of it came from areas which were supposedly worked out. Inasmuch as this ore has been found in old stoped areas which have settled and show considerable crushing at some points, the mining of the ore has been difficult and slow.

Other operations have produced some tonnage from No. 1 shaft, notably a lessee operation on the 600-foot level. Ore pulled from the caved No. 2 Portland stope has run 1 ounce per ton consistently, after screening. A production of a car of screenings and several cars of coarse ore (low grade) has been made from this lease each month.

The only profitable production from No. 2 Portland shaft has been from lessee's operations on the vein above 1,700, situated north and east of No. 2 shaft. A number of good shipments have been made from small stopes 50 feet or more above the 1,700-foot level. One shipment of screenings ran 3.62 ounces, or over \$100.00 per ton. Several others ran more than 2 ounces per ton.

Ore from a stope on the Wisconsin vein on 1,700, from the "breccia vein" on 700 and 800, returned little or no profit. The Wisconsin operation has been abandoned since. The low grade from the "breccia vein" was largely mined in prospecting work.

During the summer and fall a considerable amount of work was done on the Portland surface plant to improve it and lessen the fire hazard.

The old store-room building, engine room at No. 1, boiler room at No. 1, shaft-house building, and several old ore bins which were no longer in use, were wrecked. Several other small buildings were built or remodeled to make them nearly fireproof.

The headframe and first 30 feet of No. 1 shaft were in very poor condition and were repaired. The shaft was lined with concrete from surface down to bedrock, so that it is permanently repaired this far down.

The Portland compressor plant was in a very poor location at No. 2 shaft. It was difficult to get supplies in and make repairs. The building has been in danger of being covered up by tailings from the old mill on top of the hill, and sand blowing around during windstorms has caused unnecessary wear on the equipment.

Consequently, a new completely fireproof compressor plant has been established at No. 1 shaft, and is now in operation. The building is constructed of cinder blocks and equipped with a steel truss roof and steel doors and windows. The compressors are equipped with air filters now, and this should add materially to their life.

The unused buildings at No. 2 shaft are also being torn down, 22 sets of lessees are working through company-operated shafts, 5 sets through the Independence, and 14 sets are working elsewhere on the property exclusive of dump lessees.

Rose Nicol.—The company is operating on the 8th level of the Rose Nicol mine, and is making quite a large production of low-grade ore.

A raise from the 17th to the 14th level of the Cresson mine was completed, and in this raise they have four sublevels, all of which are producing a good grade of ore from Trail ground. This has been the best source of production for the United Gold Mines Co. during the past year, and Mr. William Petrie deserves much credit for this work.

Vindicator and Theresa.—The Theresa has been operated exclusively by split-check lessees, and during the year the United Gold Mines Co. has received a nice profit from this operation, and the mine looks quite promising for the coming year.

Since the first of the year 1936 the Vindicator has conducted a campaign of development on the 21st level. Pumps to take care of 1,500 gallons of water per minute were installed in January 1936, and since that time about 1,200 feet of drifting and crosscutting has been done on company account.

The La Bella vein was encountered and an ore shoot opened for a distance of 135 feet. This was stoped out on company account, but, due to the fact that the ore was very low grade, this was not a profitable operation. Since that time the level has been turned over to split-check lessees and an ore shoot on the Lilly vein between 2,100 and 2,000 has been discovered, which is being worked profitably by Wade & Co.

Miles Fleetwood and associates have opened an ore shoot on what is presumed to be the Carr vein for a distance of about 125 feet, and they have values in both the north and south breasts. This has all indications of being a profitable operation for both the company and the lessees. In fact, there is, from all appearances, a bright prospect for the Vindicator for 1937.

¹ Published report covers 10 months only. Figures for November and December added by the staff of the Bureau of Mines from information furnished by the United Gold Mines Co.

The annual report of the Cresson Consolidated Gold Mining & Milling Co. for the 12 months ended December 31, 1936 (dated February 15, 1937), says:

During the 12 months 61,563 dry tons of ore were shipped on company account of a gross value of \$465,411.88, averaging \$7.56 per ton; the returns, less transportation and treatment of \$219,901.86, were \$245,510.02, giving the ore a net value of \$3.99 per ton. The company received as additional income the sum of \$1,123.54 interest on bank deposits and notes, and \$192,956.18 net royalty on 58,215 tons lessee ore, in addition to \$1,541.67 dividend from the Elkton Co., making a total of \$441,131.41, with total expenses of \$342,104.21, resulting in a net gain from operations of \$99,027.20.

During the past year the development on your property has been encouraging.

On the upper levels some large low-grade stopes were opened and small chutes of better ore.

The water was pumped from the eighteenth level. New work on this level has opened 100 linear feet of ore which is above average grade and gives promise of having considerable width. In places it is now 12 feet wide and ore in both

walls. Other development on this level is being pushed. The water has fallen off in volume pumped.

The Dante and Gold Sovereign claims were operated by lessees, who shipped a large tonnage of low-grade ore.

	<i>Development</i>	<i>Feet</i>	<i>Feet</i>

The 18th level, the first level below the Roosevelt Tunnel, was unwatered in September 1936. This level had not been worked since June 1929. Before any development work could be undertaken, a large amount of retimbering and clean-up work was necessary to reach all parts of this level, which was found to be in very bad condition. This work is still being carried on.

The most encouraging development on the property, at the present time, is the 18th level development work, since the level was unwatered, which has resulted in the opening of two bodies of medium-grade ore. Work has not progressed far enough at this time to estimate their tonnage or value, but they look very encouraging.

Development of the upper levels has opened small bodies of ore on the 17th, 14th, 13th, 12th, and 9th levels. A small ore body of very good grade has been opened between the 12th and 13th levels.

Twenty-six sets of split-check lessees are at present working through the Cresson shaft, most of whom are producing some ore. In addition, the Dante and Gold Sovereign shafts are under lease on a graded royalty basis. Both these lessees have done considerable development work and shipped a large tonnage of low-grade ore.

At the present time, the most favorable outlook for new ore seems to be on the deeper levels.

The average cost per ton shipped by company and lessees during 1936 was \$2.85, on a total of 119,779 tons.

¹ The company annual report for 1935 gave \$25,952,895.85, which was corrected by letter from the company dated July 23, 1936, to read \$25,964,986.51.

² Represents 33.33 percent of the gross value and 48.71 percent of the net value.

The annual report of the Golden Cycle Corporation dated March 10, 1937, for the calendar year ended December 31, 1936, contains the following paragraphs regarding the corporation's mining operations in the Cripple Creek district.

The shaft on the Ajax has been sunk from the 21st level to the 24th level, 375 feet, and is now being continued to a depth of 500 feet below the 21st level, where a pump station will be made. From this station a crosscut will be made to cut the Mohican, New Market and Little Montana veins. The Mohican has been disappointing on the 22nd and 23rd levels, but New Market has higher values on 23rd than on 21st level. The cost of sinking was increased by a large flow of water, and the mine showed only \$12,958.46 net gain for 1936, after depreciation and depletion. However, there is a large amount of developed ore which is being mined and shipped, and we hope 1937 will show a substantial profit.

The Anchoria-Leland has shown a gain for 1936 of \$10,154.81 net, after depreciation and depletion, and on the 300 level has opened an ore shoot of good value 225 feet long. Also one lessee has a large stope of low-grade ore.

Data for the following table were taken from the annual reports for 1936 issued by the three companies named.

Production in 1936

Company	Net tons	Gross value	Royalty	Lessees	Average gross value per ton
Dr. Jack Pot Mining Co.	14, 317	\$70, 356. 84	\$4, 287. 12	\$19, 700. 48	\$4. 91
Empire Lee Mining Co.	21, 453	121, 055. 47	7, 556. 55	42, 758. 71	5. 64
The New Gold Dollar Mining Co.	3, 872	29, 457. 27	2, 200. 01	11, 094. 26	7. 61

Nearly all the output from the Stratton Estate was made by companies and individuals that leased the various mines under the royalty system and conducted their own operations, either mining on company account or subleasing to split-check lessees.⁴ The largest pro-

⁴ Under a split-check lease, the operating company furnishes the hoisting power, explosives, timber, and all other supplies and the lessee provides the labor; the net proceeds from the mill (not including royalty) are divided equally between the two.

ducers of gold, in order, were the Logan mine, Orpha May, Geneva, Moon Anchor, American Eagles, Specimen, and Los Angeles. Among other producers were the Abe Lincoln mine, Block 98, Longfellow, Porcupine, and War Eagle. The total development work done at all properties on the Stratton Estate during 1936 was 14,311 feet, of which 10,779 feet were done by the two largest producing companies—the International Gold Producers, Inc., and the Orpha May Mining Co. After the closing of the Cripple Creek mill in January 1937 ores from the Stratton properties were again shipped to the Golden Cycle mill at Colorado Springs.

The Cameron Gold Mines, Inc., continued production from the Cameron Townsite and Pinnacle group throughout 1936. Development work done comprised 100 feet of sinking on the main Cameron shaft and 1,456 feet of drifts and crosscuts. The Hidalgo Gold Mines, Inc., shipped ore continuously from the El Paso group, in which it has the controlling interest, and the Victor mine (Smith-Moffat Mines Co.) operated under lease. Approximately 3,000 feet of drifts and crosscuts were driven at the El Paso group. Lessees operated the Elkton group continuously. The Elkton Co. acquired the property of the Raven & Beacon Hill Gold Mining Co. in Arequa Gulch, comprising about 21 acres adjoining the Elkton property. W. D. Wade & Co. shipped a large tonnage of dump ore from the Empire Lee property. Thomas Kavanaugh operated his cyanide leaching plant at the Iron Clad mine continuously. The Blue Moxie Gold Mining Co. reopened the Blue Bird mine, beginning development work in the mine July 10 and shipments of ore later in the year. The Winfield Mining Co. operated the Queen group most of the year and shipped the ore produced to the Cripple Creek mill. The Joe Dandy Mining Co. repaired the shaft and buildings and started development work at the Joe Dandy mine, from which lessees shipped ore during part of the year.

Among other producers in the Cripple Creek district in 1936 were the Acacia Gold Mining Co. (Morning Star and North and South Burns), Amanda, Atlas Gold Mines Co. (Midget-Bonanza King), Black Belle, Caledonia, Commonwealth Gold, Inc., Delmonico, Economic mill dump, Forest Queen, Free Coinage Gold Mining Co., Friday, Golden Conqueror Mines, Inc., Hiawatha, Index group, Jerry Johnson, LeClair Consolidated Mines Co. (Mary McKinney), Ramona, Reba Lee Mining Co. (Mohawk), Requa Savage group, Rigi group, Rubie, Sangre de Cristo Tunnel, Santa Rita Mines Co., School Section 16, Strong Mining Co., Teutonic, Unity Gold Corporation (Katinka group), and Volcano.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN THE EASTERN AND CENTRAL STATES

The output of gold, silver, copper, lead, and zinc from mines in the Eastern and Central States increased in 1936. The advances in gold and silver were not large, but copper increased more than 17,000 tons, lead nearly 17,000 tons, and zinc nearly 39,000 tons. Owing to the higher prices for copper, lead, and zinc, the total value of the metal output was much greater in 1936 than in 1935. There were no new large producers of copper, lead, or zinc in 1936, but most of the larger operators expanded their output.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932-36

¹ 1935: Dry and siliceous ores (48,275 tons) yielded 7,417.41 ounces of gold and 2,244 ounces of silver, copper ore (666,667 tons) yielded 603 ounces of gold and 54,057 ounces of silver, lead-zinc ore (543,248 tons) yielded 21,804 ounces of silver, pyritiferous magnetite ore (1,048,792 tons) yielded 745 ounces of gold and 5,843 ounces of silver, and zinc ore (1,293,779 tons) yielded no gold or silver; 1936: Dry and siliceous ores (63,577 tons) yielded 8,622.76 ounces of gold and 2,231 ounces of silver, copper ore (681,931 tons) yielded 525 ounces of gold and 53,248 ounces of silver, lead-zinc ore (789,336 tons) yielded 19,737 ounces of silver, pyritiferous magnetite ore (1,267,484 tons) yielded 890 ounces of gold and 8,118 ounces of silver, and zinc ore (1,450,815 tons) yielded no gold or silver.

Gold.—The output of gold in the Eastern States was 10,377.10 fine ounces in 1936—only 886.44 ounces more than in 1935. This relatively small increase is disappointing when compared with the large gains in most of the Western States. Gold derived from siliceous ores increased from 7,417.41 to 8,622.76 ounces and that from the refining of copper bullion from 1,350 to 1,415 ounces, but the yield from placer mines decreased from 725.25 to 339.34 ounces. Four mines—one each in Alabama, Maryland, North Carolina, and Virginia—produced more than 76 percent of the total gold recovered in the Eastern States in 1936. Yields of gold were reported from 24 lode mines and 47 placers in 1936 compared with 37 and 64, respectively, in 1935. None of the placer mines in 1936 yielded as much as 100 ounces of gold. The estimated output of gold in the Southern Appalachian States from 1799 to 1936, inclusive, is recorded as 2,504,936 fine ounces valued at \$52,128,885.

In 1936, 63,577 tons of siliceous ore (from mines in Alabama, Georgia, Maryland, North Carolina, South Carolina, and Virginia) were treated, of which 63,009 tons were treated at gold and silver mills and 568 tons (mainly from North Carolina) were shipped crude to smelters. Gold concentrates amounting to 2,262 tons shipped to smelters yielded 6,362.28 ounces of gold, whereas bullion from gold milling plants yielded only 1,674.28 ounces of gold. Copper concentrates shipped to smelters yielded 1,250 ounces of gold. In 1935, 48,275 tons of siliceous ore were treated, of which 19,987 tons went to gold and silver mills, 2,831 tons were shipped crude to smelters,

and 25,457 tons were sent to all-flotation mills. Crude siliceous ore shipped to smelters yielded 586.20 ounces of gold in 1936 compared with 2,351.61 ounces in 1935.

No mines in the Central States yielded any gold in 1936 or 1935.

Silver.—Of the silver (83,350 ounces) produced in the Eastern States in 1936, 16 ounces came from placer bullion, 145 ounces from bullion recovered at gold and silver mills, 71,569 ounces from concentrates smelted, and 11,620 ounces from crude ore shipped to smelters. Siliceous ores yielded 2,231 ounces, placer mines 16 ounces, lead-zinc ores from New York and Tennessee 19,737 ounces, and copper ore 53,248 ounces; the rest of the silver came from copper concentrates recovered by flotation from pyritiferous magnetite ore.

The production of silver in the Central States in 1936 totaled 165,500 ounces. The output in Illinois (1,780 ounces) came from galena concentrates recovered in milling fluorspar, and that in Missouri (163,720 ounces) was from the refining of lead bullion, slags, and skimmings recovered from the lead ores of southeastern Missouri.

Copper.—The mine production of copper in the Eastern States was 22,907,700 pounds valued at \$2,107,508 in 1936 compared with 20,813,111 pounds valued at \$1,727,488 in 1935. The output of copper from Tennessee mines increased about 2,000,000 pounds and that from Pennsylvania about 600,000 pounds. The Bureau of Mines is not at liberty to show the copper production by States. The gold concentrates shipped to smelters from Alabama and North Carolina yielded small quantities of copper, but most of the copper was derived from copper ore mined in North Carolina and Tennessee and from copper concentrates recovered from Pennsylvania pyritiferous magnetite ore mined for its iron content. The output of copper from gold concentrates in 1936 was 67,900 pounds. The copper ore yielded about 0.008 ounce of gold and 0.08 ounce of silver to the ton of crude ore. The copper concentrates from the magnetite ore contained about 25.6 percent copper and about 0.10 ounce of gold and 0.91 ounce of silver a ton.

The copper output of the Central States came from copper ore from Michigan and lead ore from Missouri; no copper ore was shipped from Missouri in 1936 or 1935, and the copper reported was derived from the treatment of residues from lead smelted. The output of refined copper in Michigan increased from 64,108,689 pounds in 1935 to 95,968,019 pounds in 1936, whereas the average recovery per ton of rock declined from 46.6 to 29.8 pounds.

Lead.—The lead produced from mines in the Eastern States in 1936 came from lead-zinc ores from the Austinville mine in Virginia, the Balmat mine in New York, and the Embree mine in Tennessee; a little lead was reported produced in North Carolina in 1936. Shipments of galena concentrates totaled 9,199 tons and yielded 5,996 tons of lead—1,014 tons more than the yield in 1935.

The lead recovered from shipments of lead ore and concentrates in the Central States increased from 132,682 tons in 1935 to 148,536 tons in 1936, due mainly to increased shipments from southeastern Missouri and from the Tri-State region in Oklahoma and Kansas. Missouri shipments yielded 110,428 tons of lead in 1936 compared with 97,493 tons in 1935. Recovered lead in shipments from Oklahoma mines totaled 25,427 tons in 1936 and 23,405 tons in 1935, and shipments of lead concentrates from Kansas mines yielded 11,409 tons of lead in 1936 and 10,892 tons in 1935. Wisconsin mines

produced ore yielding 904 tons of lead in 1936 and 286 tons in 1935. Lead production of Kentucky decreased from 132 tons in 1935 to 50 tons in 1936, that of Illinois from 436 to 294 tons, and that of Arkansas from 38 to 24 tons. Mines in the Tri-State or Joplin region shipped 52,256 tons of lead concentrate yielding 38,842 tons of lead in 1936.

Zinc.—The recoverable zinc in ore and concentrates shipped from mines in the Eastern States was 161,740 tons valued at \$17,053,710 in 1936 compared with 158,260 tons valued at \$15,789,457 in 1935. Mines in New Jersey yielded nearly 90,000 tons as metal or in oxide valued at \$9,868,010.

[N. B.—The value of the zinc in New Jersey is the estimated smelting value of the recoverable zinc content of the ore after freight, haulage, smelting, and manufacturing charges are added.]

Mines in New York increased their output of recoverable zinc from 23,720 tons in 1935 to 26,941 tons in 1936. The zinc is partly from zinc ore and partly from lead-zinc ore. Zinc sulphide ores yielded all the zinc from Tennessee except that derived from about 4,280 tons of zinc carbonate ore mined and shipped. The recovered zinc content of sphalerite concentrates shipped from mines in Virginia may not be disclosed, but that of concentrates shipped from Tennessee and Virginia in 1936 was 44,916 tons. There was a decrease in the output from Virginia but a small increase in that from Tennessee.

Zinc concentrates shipped from mines in the Central States had a recoverable zinc content of 235,447 tons in 1936 compared with 200,339 tons in 1935. Mines in the Tri-State region shipped ore and concentrates yielding 226,857 tons of zinc in 1936 (191,136 tons in 1935), of which Oklahoma contributed 57 percent and Kansas 35 percent. Stocks of sphalerite were negligible at the end of 1936. The recoverable zinc in shipments from Wisconsin decreased from 8,923 tons in 1935 to 8,126 tons in 1936; it increased in shipments from Missouri mines from 7,263 to 18,709 tons. In 1935, all the Missouri zinc came from southwestern Missouri, but in 1936 a small shipment of sphalerite was made from southeastern Missouri. Illinois mines shipped no zinc concentrate in 1936. Recoverable zinc from Kentucky increased from 127 to 238 tons. Arkansas shipments of zinc carbonates continued small; the recovered zinc increased from 153 to 182 tons.

MINE PRODUCTION IN THE EASTERN STATES

Alabama.—The quantity of gold produced in Alabama from 1830 to 1936, inclusive, is recorded as 46,949.37 fine ounces. The yield in 1936 was 4,726 ounces and was mainly that of the Hog Mountain Gold Mining & Milling Co., in Tallapoosa County, 13 miles northeast of Alexander City, which mined and treated about 48.5 percent of all the siliceous ore treated in the Appalachian States in 1936. The exact production of the Hog Mountain mine is not known, but the output from 1839 to 1915 was probably \$250,000. The mine was idle from 1845 to 1896; it was then reopened, a 75-ton cyanide plant was erected, and about 100,000 tons of ore were treated between 1896 and 1916 when the mine was abandoned; it was not reopened until 1933. The sulphide ore now being mined is treated at a 150-ton all-flotation plant first operated in February 1934. The crude ore contains about 0.20 to 0.22 ounce of gold to the ton, with traces of copper and silver. The concentrates, which are shipped to the Nichols Copper Co., yield about 2.75 ounces of gold and 0.42 ounce of silver to the ton and 0.62

percent of copper. The mine and mill were operated steadily in 1936 and a total of 310,000 man-hours was worked. The mine is equipped with a double-compartment shaft 215 feet deep; 1,119 feet of development work were done in 1936. Mining and milling methods at the Hog Mountain mine are given in a recent publication² of the Bureau of Mines.

The Gold Log mine 9 miles west of Talladega was not operated in 1936. The property has been acquired by the Guy S. Amos Mining Co. There is a 320-foot shaft at the mine, and a 100-ton amalgamation and flotation plant is under construction in 1937.

Georgia.—The quantity of gold produced in Georgia from 1830 to 1936, inclusive, is recorded as 866,922 fine ounces. In 1936, 35 placers and 2 lode mines yielded a total of 449.57 ounces of gold and 28 ounces of silver. Of the 304.26 ounces of placer gold produced, 77.57 ounces came from mines near Dahlonega and Auraria in Lumpkin County, 183.51 ounces from mines near Sautee, Nacoochee, and Helen in White County, and the remainder from small mines in Carroll, Cherokee, Hall, Paulding, Rabun, Union, and Wilkes Counties. The larger shippers of placer gold in 1936 were the Ferey Gold Mining Co., Dixie Gravel Co., T. J. Stevenson, and H. L. Schwalbe, all in White County. Gold recovered from less than 200 tons of siliceous ores amounted to 145.31 ounces, mainly from the Battle Branch and McDonald mines at Dahlonega in Lumpkin County. The Battle Branch mine was operated by the Southern Mineral Development Co. The company has a 10-stamp amalgamation concentration mill; no concentrates were shipped in 1936, but about 550 feet of development work were done. The McDonald mine is an open-cut operation equipped with a 5-stamp amalgamation plant. The property of the 301 Mining Co. at Hollysprings in Cherokee County was idle in 1936, but it is probable that the 12-stamp amalgamation-concentration plant will be operated in 1937. Lessees of the Barlow mine at Dahlonega were testing methods of operating it. Other properties at Dahlonega controlled by Dr. Craig R. Arnold awaited construction of milling equipment. The Capps and adjoining properties, including the Crown Mountain, were acquired by O. S. Sykes, who is endeavoring to finance the group and construct a large mill. The Burnt Hickory Mining Co. of Atlanta operated a mine near Dallas in Paulding County and recovered some gold by sluicing; the mine was operated for a few months only and was closed in the fall of 1936 for installation of a power shovel and a machine for washing gravel.

Maryland.—The total gold production of Maryland to the end of 1936 is estimated at 4,135.71 fine ounces. Until 1936 no gold had been produced in Maryland for many years, but in 1935 the Maryland Mining Co. did some development work in Montgomery County and in 1936 was the third largest producer of gold from gold ore in the Eastern States. No expensive plant or buildings have been erected, the milling equipment consisting of a small stamp and amalgamation concentration plant built for experimental purposes. The mine is equipped with a 200-foot, three-compartment shaft, and ore is mined at the 150- and 200-foot levels. A small shipment of concentrates was made in 1936 to Carteret, N. J., but excessive charges for freight, etc., on this shipment resulted in the holding of other concentrates pending

²Johnson, N. O., Mining and Milling Methods and Costs, Hog Mountain Gold Mining & Milling Co., Alexander City, Ala.: Inf. Circ. 6914, Bureau of Mines, 1936, 23 pp.

their treatment at the property. A considerable part of the gold was panned from rich ore; the ore treated at the mill ran about \$17 to the ton; and the tailings were impounded for future treatment. The bullion sent to the mint was 950 fine and contained very little silver. The property controlled covers about 250 acres and is said to show numerous veins of good ore. The conservative operation of the company has attracted considerable attention to the fact that the property is being worked close to the boundaries of the District of Columbia.

New Jersey (see also note on p. 348).—The production of zinc ore in New Jersey in 1936 was 526,233 tons containing 89,883 tons of recoverable zinc as metal or in oxide. The only producing properties were the Sterling and Mine Hill mines; these mines were operated about 257 days in 1936 and have a much larger potential output.

New York.—The quantity of zinc ore mined and treated in New York increased from 80,731 tons in 1935 to 92,749 tons in 1936 and that of lead-zinc ore from 214,448 to 284,702 tons. The concentrates shipped yielded 26,941 tons of zinc and more than 1,000 tons of lead; the lead concentrates from the Balmat mine contain considerable silver also. The Balmat mine is near Sylvan Lake; it produces lead-zinc ore, is equipped with a 1,200-ton all-flotation concentration plant, and has a shaft 900 feet deep. The shaft at the Edwards mine is 1,900 feet deep, and the all-flotation plant has a capacity of 330 tons. About 170 men were employed 312 days at the Balmat mine and mill, and about 85 men worked 312 days at the Edwards mine.

North Carolina.—The quantity of gold produced in North Carolina from 1799 to 1936, inclusive, is recorded as 1,151,850.27 fine ounces. The yield in 1936 was 2,037.17 ounces, of which 28.37 ounces came from nine placers and 2,008.80 ounces from nine lode mines. The output of silver was 5,575 ounces, of which 1,171 ounces came from placers and lode-gold mines and the remainder from copper ore. The Fontana copper mine was the largest producer of silver and the second largest producer of gold in North Carolina in 1936, although the assay content of gold and silver in ore shipped from this mine is very low. The meager output of placer gold came from mines in Cabarrus, Catawba, Guilford, Iredell, Randolph, Rutherford, and Union Counties. None of the properties yielded more than a few ounces. Much the largest producer of lode gold in North Carolina in 1936 was the Rudisil mine, the second largest producer of gold in the Appalachian States. The lode gold came from mines in Cabarrus, Franklin, Gaston, Mecklenburg, Randolph, Stanly, and Swain Counties.

The North Carolina Exploration Co. shipped crude sulphide copper ore from the Fontana mine in Swain County to the Tennessee Copper Co. smelter at Copperhill, Tenn.; the ore is said to average 0.009 ounce of gold and 0.23 ounce of silver to the ton. Most of the gold production of North Carolina in 1936 was that of the Rudisil Gold Mine, Inc., operating a mine and mill near Charlotte, in Mecklenburg County. The sulphide ore containing gold, silver, and a little copper was treated at a 50-ton flotation mill. The concentrates and some crude ore were shipped to Carteret, N. J., for smelting. The mine is opened by a 300-foot vertical shaft, and about 300 feet of development were done in 1936. The Allen Furr mine in Cabarrus County near Stanfield was operated by Midas Mines, Inc.; concentrates shipped to Carteret contained about 0.76 ounce of gold and 5 ounces

of silver to the ton. The Portis mine in Franklin County, owned by the Norlina Mining Co., was leased to the Appalachian Gold Corporation; it yielded some gold from a stamp and amalgamation mill. The Snyder mine in Cabarrus County was operated by A. L. Nash part of 1936, and some dump ore was treated at a 5-stamp mill. R. L. Stover of Belmont, Gaston County, shipped a car of ore to Carteret for treatment. The Keystone Mining Co. operated the Jones and Keystone mines near Fullers in Randolph County; the ore was taken from open-cut workings and treated at a 120-ton amalgamation-flotation plant. The H & G mine in Randolph County was operated a short time by H. L. Griswold, and some bullion was shipped. The Thompson mine near Albemarle in Stanly County was worked by Cohen Bros., and small shipments of bullion were made to the Philadelphia Mint. The Hoover Hill Mining Co. operated its property in Randolph County about 126 days in 1936; development work only was done. The Keystone Mining & Milling Co. continued development work at its property at Union Mills in Rutherford County but did not operate its milling plant. Apparently no ore or bullion was shipped from properties in the Gold Hill district in Rowan County.

Pennsylvania.—The Cornwall mine in Lebanon County was operated at a greatly increased rate in 1936, and more than 8,900 tons of copper concentrates were shipped. The ore is pyritiferous magnetite, and the tailings from the iron concentrates go to a flotation plant; the copper concentrates, which contain about 25 percent copper and 0.10 ounce of gold and 1 ounce of silver to the ton, were shipped to the Nichols Copper Co. The mine has an open-cut, an inclined shaft, and 1,500 feet of drifts; it was operated about 295 days in 1936, the concentrating plant 340 days.

South Carolina.—From 1829 to 1936, inclusive, mines in South Carolina yielded 254,249.72 fine ounces of gold. The output in 1936 from five lode mines and two placers was 287.39 ounces, of which 282.22 ounces came from lode mines and 5.17 ounces from placers. Gold-milling plants recovered 233.22 ounces of gold and 36 ounces of silver, and 85 tons of crude ore shipped to smelters yielded 49 ounces of gold. The lode mines yielded 49 ounces of silver and the placers 1 ounce. Ten gold mines milled or shipped about 12,535 tons of siliceous ore. The large decline in output of gold in 1936 was due to the decrease in crude ore shipped to smelters; the Dickey mine in Cherokee County near Smyrna was the only shipper of crude ore in 1936. The Terry mine, also near Smyrna and formerly operated by Shorey C. Guess, was idle in 1936. The old Haile mine in Lancaster County near Kershaw had a comparatively small output; however, it yielded nearly all the gold produced from lode mines. The 50-ton amalgamation plant was closed in April 1936, but the operators have completed plans for the construction of a 250-ton cyanide plant. The first unit of this plant was expected to be in operation by April 1, 1937, and the second unit by August 1. The mine is reported to have yielded about \$3,200,000 since 1828. It has been worked by an open-cut about 80 feet deep. The Hayes Gold Mining Co. in Lancaster County at Kershaw mined some ore which was treated at a small pilot mill; the company expects an increased output when a larger mill is operated in 1937. The Thirty-Five Mining Co. at Hickory Grove, York County, did not mill or ship any ore in 1936 but carried on development throughout the year. The shaft at the mine is 106 feet deep, and about 500 feet of drifts were run in 1936. No

milling plant will be constructed until further development is done. The Southern Gold Mining Co. and the White Star Milling Co. made little output.

Tennessee.—Mines in Tennessee produced 18,975.88 fine ounces of gold from 1831 to 1936, inclusive; almost the entire output since 1906 has come from copper ore, and copper bullion was the sole source of the 410 ounces produced in 1936. The output in 1935 was 423 ounces. The quantity of silver recovered from copper ore increased from 47,151 ounces in 1935 to 50,330 ounces in 1936. The Embree Iron Co., the only producer of lead in Tennessee in 1936, shipped four times as much lead concentrate as in 1935. The production of copper increased considerably, and that of zinc was about 700 tons more than in 1935.

The total output of copper from mines in Tennessee, North Carolina, and Pennsylvania was 22,893,700 pounds in 1936 compared with 20,802,110 pounds in 1935; the large increase came from mines in Tennessee and Pennsylvania. The total lead recovered from mines in Tennessee, New York, Virginia, and North Carolina was 5,996 tons in 1936 compared with 4,982 tons from Tennessee, New York, and Virginia in 1935; about 600 tons of the increase came from Tennessee and the remainder from Virginia. The total zinc recovered from mines in Tennessee and Virginia was 44,916 tons in 1936 compared with 48,832 tons in 1935. The Bureau of Mines is not at liberty to publish figures for the foregoing States separately.

The Tennessee Copper Co. ran its 1,200-ton-per-day flotation plant and smelter continuously in 1936 on ore from the Burra Burra mine in Tennessee, on sulphide ores from the Fontana mine in Swain County, N. C., and during the latter part of the year on ore from the Isabella mine in Tennessee; very little ore was received from mines in other States. The zinc concentrates, averaging 49 percent zinc, were shipped to the American Steel & Wire Co. plant at Donora, Pa.; the copper bullion was sent to the Nichols Copper Co. The Ducktown Chemical & Iron Co. operated its Isabella mine and 700-ton flotation plant until August 31 (172 days) and shipped the concentrates to the Nichols Copper Co. The entire property of the company at Isabella was acquired the last of August by the Tennessee Copper Co., which operated it after that time. The Mascot mine and mill of the American Zinc Co. of Tennessee were operated 283 days. The mine is opened by a shaft, and the average depth of mining is 500 feet. The output of zinc was greater than in 1935. The Universal Exploration Co. mine in Jefferson County was worked steadily but not at capacity in 1936. The large 800-ton all-flotation mill was operated 293 days on sulphide ore from two shafts about 200 feet deep. The carbonate zinc ore was mined 220 days; it was treated at a 100-ton mill not equipped for flotation. The average grade of the carbonate concentrates was 41.87 percent zinc and that of the sphalerite concentrates 64.57 percent. This sphalerite is probably of higher grade than that shipped from any other mine in the United States. The Embree Iron Co. in Washington County shipped less zinc carbonate in 1936 than in 1935 but increased greatly the quantity of lead carbonate ore shipped to smelters. The mine and log washer were operated steadily throughout the year.

Virginia.—The quantity of gold produced from Virginia mines from 1828 to 1936, inclusive, is recorded as 161,853.50 fine ounces, of which only 2,767 ounces were produced during the past 25 years. In 1936

the output of the State was 908.97 ounces of gold and 96 ounces of silver from three lode mines and one placer. Shipments of zinc concentrates decreased in 1936 and those of galena concentrates increased about 600 tons, but the Bureau of Mines is not at liberty to publish the figures for zinc or lead output as the Austinville mine of the Bertha Mineral Co. is the only producer of lead-zinc ore in Virginia. The mine and 1,200-ton concentration flotation mill were operated steadily throughout the year; about one-third of the mill output comes from flotation.

Most of the gold output of Virginia in 1936 came from the Vauluse mine near Wilderness in Orange County, operated by the Virginia Mining Corporation. This mine has a vertical shaft 300 feet deep, and 1,000 feet of drifts were run in 1936. The sulphide ore is treated in a 90-ton all-flotation plant, and the concentrates are shipped to Carteret, N. J. The milling plant, pumps, hoists, etc., are operated electrically. The mine was worked 240 days and the mill 100 days. The Moss Mining Co. operated a lode mine, equipped with a 25-ton amalgamation plant, at Tabscott in Goochland County. The gold recovery was good considering the small quantity of ore milled. The Peabody Mining Corporation in Goochland County was the only operator of placer property in Virginia in 1936. No output was reported from the Ruth placer of the Powhatan Mining Corporation, also in Goochland County.

MINE PRODUCTION IN THE CENTRAL STATES

Quantity and tenor of ores.—The only fair basis for comparing the relative magnitude of mining in different States is the quantity of crude ore or "dirt." The metal content of the ores of the several mining regions and States exhibits marked differences; therefore, comparison of tenor of the ores is interesting and significant. Virtually all the ore from the Central States is of such low tenor as to require concentration. In Kentucky and southern Illinois most of the lead and zinc concentrates are recovered as byproducts in the concentration of the fluorspar that they accompany, and the metal content of the crude ore raised cannot be calculated. In Arkansas very little ore has been mined for several years, and the average tenor calculated from the output of ore during these years would not offer accurate comparison with that during a period of active mining.

Quantity and tenor of copper, lead, and zinc ores, old tailings, etc., produced in the Central States, 1934-36, by States

State	1934		1935		1936	
	Ore, etc.	Metal content ¹	Ore, etc.	Metal content ¹	Ore, etc.	Metal content ¹
	<i>Short tons</i>	<i>Percent</i>	<i>Short tons</i>	<i>Percent</i>	<i>Short tons</i>	<i>Percent</i>
Kansas.....	2,098,700	2.67	2,900,100	2.41	4,644,800	2.09

	12,447,755	-----	15,396,803	-----	21,530,800	-----

¹ The percentages represent the metal content of the ore insofar as it is recovered in the concentrates. In Michigan the metal so recovered is copper; in other Central States the metals are lead and zinc combined, the relative proportions of which are shown in the table on p. 344 and in the tables of tenor of ore given in the sections devoted to the respective States.

Production of lead and zinc by regions.—The report of this series for 1930 (chapter of Mineral Resources of the United States, 1930, pt. I) gives the areas included in the seven lead- and zinc-producing regions of the Central States. Mineral Resources, 1914, contains brief reviews of the history of lead and zinc mining in the Central States, the yearly production of each State from 1907 to 1914, inclusive, and historical notes and estimates of the total production of lead and zinc in each State before 1907. Subsequent records year by year are found in Mineral Resources and Minerals Yearbook.

¹ Includes galena and a small quantity of lead carbonate concentrates.

² Includes sphalerite and a small quantity of zinc carbonate and zinc silicate concentrates.

³ Includes Iowa, northern Illinois, and Wisconsin.

⁴ Includes some lead-zinc ore.

REVIEW BY STATES

Arkansas.—In 1936, 494 tons of zinc carbonate and mixed zinc carbonate and sulphide were shipped from about 10 mines in Arkansas; the recoverable zinc in the concentrates was 182 tons. In 1935, 435 tons of zinc carbonate were shipped. None of the mines gave any data for 1936 on their operations or shipments, but the smelters that purchased the concentrates gave the information. Shipments of zinc concentrates were made from the Lonnie Boy and other mines of the Urschel Lead & Zinc Co., the McIntosh mines, and the Edith mine, all in the Rush district; other shipments were made of small lots purchased from scrappers in the Kingdom, Hall Mountain, and Dodd City districts. The only shipments of lead concentrates from Arkansas in 1936 were about 30 tons purchased by the Eagle-Picher

Mining & Smelting Co. from the Ponca district; the recoverable lead content was 24 tons. The higher prices now being paid for zinc carbonate and galena concentrates may increase shipments from Arkansas in 1937, although the Urschel mill at Rush was burned in October 1936.

Illinois.—No lead or zinc mines in Illinois were operated in 1936 or 1935. Shipments of galena from fluorspar mines in southern Illinois in 1936 totaled 410 tons of galena concentrates having an average lead content of 73.2 percent; 294 tons of lead and 1,780 ounces of silver were recovered from these shipments compared with 436 tons of lead and 3,147 ounces of silver recovered in 1935. The Hillside Fluor Spar Mines at Rosiclare was the largest shipper in both 1936 and 1935.

Kansas.—Shipments of galena concentrates from mines in Kansas totaled 14,789 tons having a recoverable lead content of 11,409 tons in 1936 compared with 14,301 and 10,892 tons, respectively, in 1935. The quantity of sphalerite concentrates shipped was 149,095 tons with a recoverable zinc content of 79,017 tons in 1936 compared with 102,078 and 54,110 tons, respectively, in 1935. The total quantity of concentrates made by flotation was 62,550 tons of sphalerite and 2,730 tons of galena in 1936 compared with 51,770 and 5,712 tons, respectively, in 1935. The total number of lead and zinc mines operated in Kansas in 1936 was about 50. The number of milling plants operated was less than 30.

Mine shipments of lead and zinc in Kansas, 1935-36

Year	Lead concentrates		Zinc concentrates		Metal content ¹			
					Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1935.....	14,301	\$579,690	102,078	\$2,948,509	10,892	\$871,360	54,110	\$4,761,680
1936.....	14,789	765,746	149,095	5,473,457	11,409	1,049,628	79,017	7,901,700

¹ In calculating the metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

Tenor of lead and zinc ore and old tailings milled and concentrates produced in Kansas, 1935-36

	1935		1936	
	Crude ore	Old tailings	Crude ore	Old tailings

Sphalerite concentrates.....	29.26	26.81	32.22	30.27

There was only a small output from the Lawton camp; it was made by small operators using hand jigs or from crude ore trucked to the Playter custom mill at Waco. The 2,800 tons of crude ore yielded 15 tons of galena and 156 tons of sphalerite concentrates. Virtually no mining was done at the Crestline camp, and the output in the Kansas part of the Waco area was almost entirely from tailings treated at two mills—the Bailey Mining & Milling Co. and the R. H. & G. Mining Co. The two mills operated only a part of 1936 and shipped 2,118 tons of sphalerite. No output of lead was reported. The total output of all the above camps in 1935 was 66 tons of galena and 3,212 tons of sphalerite. Operations at the old Galena camp in both 1936 and 1935 were confined to scrapping and the treatment of dump ore. The output was about 62 tons of galena and 178 tons of sphalerite in 1936 and 310 tons of lead concentrate and 70 tons of sphalerite in 1935. Mines and mills near Baxter Springs shipped 3,092 tons of galena and 22,052 tons of sphalerite in 1936 compared with 5,598 and 15,814 tons, respectively, in 1935. The St. Louis Smelting & Refining Co. was the largest producer of galena and sphalerite in this area in 1936. Considerable drilling was done late in the year, and operations will be extended to several hundred acres where work has been dormant for several years. In 1936 the large producers from tailings were the Beck Mining & Milling Co., the O. W. Bilharz Mining Co., and the Baxter Chat Co. Ore was mined and milled or shipped to custom mills from the Hocker, Robob, Iron Mountain, Blue Circle, Peru, Ballard, and Wade mines. The old Peru mine was finally worked out and abandoned, and the Paxton mine, long idle, was being dewatered. Mines in the Blue Mound-Treecce area shipped 8,327 tons of galena and 82,942 tons of sphalerite in 1935 but increased their output to 11,620 tons of galena and 124,591 tons of sphalerite in 1936. Part of the 1936 shipments were of concentrates made in 1934 and 1935.

Output from the treatment of tailings and from crude ore increased; a large part of the crude ore was trucked to the Central mill in Oklahoma for treatment, including the ore from the Mid-Continent, Bendelari, Big John, Ace High, Gray Wolf, and Northern leases. The Black Eagle was purchased in April 1936 by the Mary M. Mining Co., and the mill was run partly on ore and partly on old tailings. A large quantity of the stored sphalerite at the Jarrett mine of the Federal Mining & Smelting Co. was sold in December, and the mine bins were cleaned up early in 1937. The Muncie mill of the Federal Mining & Smelting Co. was operated in 1936, but the Jarrett mill was idle. The largest producing mine in Kansas in 1936 was the Barr of the Vinegar Hill Zinc Co.; other producing properties were the Mid-Continent, No. 14 of the Evans Wallower Lead Co., Wilbur of the Commerce Mining & Royalty Co., Blue Mound of J. P. Dines, Robinson of the American Zinc, Lead & Smelting Co., Cherokee, Big Elk, and Redskin. The Big Elk mine was equipped with a new milling plant in 1936. The eight tailing mills operating in this area in 1936 made a very large output (22,519 tons) of sphalerite but only 200 tons of galena. The largest mill, that of the Captain Milling Co., treated tailings from the Wilbur and Bendelari mines; it was built in 1936.

Kentucky.—In 1936 about 10 mines in Kentucky shipped 693 tons of zinc carbonate and 96 tons of lead carbonate yielding 238 tons of zinc and 50 tons of lead. The concentrates sold were shipped largely

by Avery H. Reed, of Marion, who operated the K & K mine and also purchased ore or concentrates from the Aluminum Ore Co. and from operators of the Blue & Marble, Hudson, Davenport, Columbia, Miller, and Tyrie mines near Marion. Other shippers were the Hickory Consolidated Mining Co. operating the old Sheridan property and Roberts & Frazer who mined on Kentucky Fluorspar Co. property. The zinc carbonate shipped averaged 38 to 40 percent zinc and the lead carbonate about 50 percent lead.

Michigan.—No gold or silver was produced in 1936 or 1935 from the properties at Ishpeming. At the Michigan mine an average of 20 men was employed during most of 1936; development was done at the 270-foot level, and a 100-ton flotation plant was being installed. The Ishpeming Gold Mining Co. continued to drill and sample the old Ropes mine and adjoining land.

Copper was produced in Michigan in 1936 by the two companies that have furnished the output of the State since 1932. A total of 3,225,600 tons of rock and sands was treated and yielded 141,166,376 pounds of mineral containing 95,968,019 pounds of recoverable copper. Nearly half (1,547,000 tons) of the gross tonnage treated was sands which contained 19,167,000 pounds of recoverable copper. The large increase in tonnage of sands treated was partly responsible for the sharp drop in average copper content of rock treated in 1936 to 1.49 percent compared with 2.33 percent in 1935 and 3.44 percent in 1934. Exclusive of sands, however, the grade dropped from 3.65 percent in 1935 to 2.29 percent in 1936. The drop in grade of rock treated, exclusive of sands, was the first recorded since the policy of selective mining was inaugurated to combat depression prices.

The increasing price for copper in the latter part of 1936 led to plans for the reopening of the Quincy mine, closed since September 22, 1931. In order to reopen the property an assessment was made on the stockholders. In a letter to stockholders early in 1937 the president reported that good progress was being made in preparing the mine for production and that indications were that the mine would be in active operation by the end of March. He said—

Large reserves of copper rock were developed just prior to the depression, these reserves amounting to approximately 2,000,000 tons, and an additional 4,000,000 tons partly developed are intact in the lower levels of the mine. * * *

Mine production of gold, silver, and copper in Michigan, 1932-36¹

Year	Gold (fine ounces)	Silver (fine ounces)	Copper			Concentrate ("min- eral")		Ore ("rock") (short tons)

¹ According to Bureau of the Mint.

The following data are abstracted from reports of the companies to their stockholders.

Production of copper by the Calumet & Hecla Consolidated Copper Co. from the Conglomerate and Ahmeek mines in 1936 amounted to 59,315,000 pounds at an average cost sold (not including depreciation and depletion) of 6.20 cents a pound. The Lake Linden reclamation plant was operated continuously and at maximum efficiency. Production totaled 19,167,000 pounds of copper at an average cost sold (not including depreciation and depletion) of 4.51 cents a pound. In 1935 the Conglomerate mine produced 36,330,800 pounds of copper at an average cost of 6.07 cents, and the reclamation plant produced 9,118,000 pounds at an average cost of 4.80 cents. The average selling price was 9.80 cents a pound in 1936 compared with 8.89 cents in 1935. The Conglomerate lode, which has been operated almost continuously for 70 years and has been the principal producing unit of the company, was nearing exhaustion at the end of the year; its expected life was only 12 to 14 months. The Tamarack reclamation plant, idle since November 1930, was being reconditioned, and production was expected to begin early in the spring of 1937. The tonnage of material remaining to be treated at this plant was estimated to be sufficient for 5 years of normal operation. The tonnage remaining at the Lake Linden reclamation plant was expected to be sufficient for 7 years of normal operation. The operations of the Lake Linden plant for 1936 and from the beginning of its operations through 1936 were as follows:

Operations at the Calumet & Hecla reclamation plant at Lake Linden in 1936 and for the entire period of its operation

	1936	Since starting
Quantity treated.....short tons.....	1, 547, 000	22, 122, 000
Assay headings.....percent.....	0. 720	0. 714
Assay tailings.....do.....	. 098	. 144
Refined copper produced.....pounds.....	19, 167, 000	252, 848, 000
Refined copper produced per ton treated.....do.....	12. 39	11. 43

Of the total production in 1936, 4,352,000 pounds were from table treatment following grinding, 12,218,000 pounds from leaching, and 2,597,000 pounds from flotation.

The Calumet mill stamped 473,338 tons of Conglomerate rock and the Ahmeek mill 884,447 tons of Kearsarge lode rock. From current production and stock the smelter treated 55,602 tons of concentrates which yielded 72,490,512 pounds of copper.

Work of the company in the Ishpeming gold area continued and was directed principally toward efforts to discover the size and grade

of the old Ropes ore body and to see whether other ore bodies occur along the shear zone in which it lies. Indications were that there is a good possibility that the ore body contains about 1 million tons of ore averaging 0.13 ounce of gold and 0.70 ounce of silver to the ton. Dividends totaling \$1,504,126.50 were paid during the year, the first since 1930.

Copper production by the Copper Range Co. in 1936 was not greatly in excess of that in 1935. The Champion mine produced 17,486,019 pounds of copper compared with 16,759,889 pounds in 1935. The average cost per pound increased 0.61 cent, while the average sales price increased 0.91 cent. Through a merger agreement the Copper Range Co. acquired all the assets of C. G. Hussey & Co., as of December 31, 1936. Owing to a substantial increase in the quantity of fabricated copper products produced and sold, the Hussey company had to purchase copper from outside sources. At the close of 1936 the Copper Range Co. withdrew from the outside market and in the future will ship its entire output of copper to the Hussey plant. The operations of the company for 5 years are shown in the following table.

Copper produced by the Champion mine of the Copper Range Co., 1932-36

Year	Rock stamped	Copper produced	Yield per ton	Cost per pound ¹	Price received
	<i>Short tons</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Cents</i>	<i>Cents</i>
1932.....	291, 265	12, 188, 578	41.847	8.646	6.0

¹ Excludes depreciation and depletion.

Missouri.—The following tables show the production of lead and zinc in southwestern Missouri and the tenor of ore ("dirt") and concentrates from Missouri.

As only one large tailing mill was operated in 1936 and 1935, the Bureau of Mines is not at liberty to give detailed separate recoveries from old tailings. The 460,700 tons of crude ore milled in southwestern Missouri in 1936 yielded 0.64 percent in lead concentrates and 6.91 percent in zinc concentrates. Some slag was shipped to the Ozark Mining & Smelting Co. at Coffeyville, Kans., from the old Granby smelter.

Mine production of lead and zinc in southwestern Missouri, 1935-36

Year	Lead concentrates				Zinc concentrates				Metal content ¹			
	Galena		Carbonate		Sphalerite		Silicate		Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1935.....	490	\$19,600	345	\$10,350	13,020	\$371,980	1,400	\$20,561	552	\$44,160	7,263	\$639,144
1936.....	2,340	113,912	294	10,497	34,068	1,085,455	621	10,762	2,006	184,552	18,665	1,866,500

¹ In calculating the metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

The value of the silver, copper, lead, and zinc shipped from Missouri mines was \$12,192,221 in 1936, compared with \$8,523,659 in 1935. No silver was recovered from copper ores in 1936 or 1935, but silver skimmings from lead refining yielded 163,720 ounces of silver in 1936 and 110,551 ounces in 1935; in addition, lead ore yielded 382,000 pounds of copper in 1936 and 67,660 pounds in 1935. The quantity of recovered lead increased to 110,428 tons in 1936 from 97,493 tons in 1935 and that of recovered zinc to 18,709 tons in 1936 from 7,263 tons in 1935.

Shipments of lead concentrates (of which only 294 tons were lead carbonate) were 148,209 tons in 1936, compared with 132,240 tons in

1935. Of the total in 1936, 145,575 tons were shipped from mines in southeastern Missouri, compared with 131,405 tons in 1935. The average lead content of the galena from southeastern Missouri in 1936 was 76 percent, and the recovered lead content was 108,422 tons, compared with 96,941 tons in 1935. Small shipments of sphalerite, the first in several years, were also made from southeastern Missouri in 1936; these low-grade concentrates yielded 44 tons of zinc. Shipments of lead concentrates from southwestern Missouri mines comprised 2,340 tons of galena and 294 tons of lead carbonate in 1936, compared with 490 and 345 tons, respectively, in 1935. The comparatively large increase in galena was due to increase in the Oronogo camp.

The total value given for all concentrates is based on actual receipts by the sellers and not on quoted prices. In 1936, as in 1935, the quoted price for galena concentrates was that paid for medium-size lots, and sellers of larger than carload lots were paid \$1 to \$2 a ton above the quoted prices.

The quoted price for 80-percent galena concentrates for the first 8 weeks of 1936 was \$47; it was \$50 from March until October, when it reached \$54. The price rose \$3 a ton early in November, and advances of \$1 in each of the next 2 weeks increased it to \$59, where it remained until about December 12. It advanced then to \$64 and again to \$70 during the last 10 days of 1936.

The quoted price of sphalerite concentrates in 1936 opened at \$32 and was steady at that price for 27 weeks, gradually declining to \$30.50 early in July. It was \$31 from the last week in July to the end of August, rose to \$31.50 the first week in September, where it held for 10 weeks, reached \$32 the second week in November, and was \$32.50 the last week in that month. On December 19 the price was raised to \$35, where it remained for the rest of the year.

No prices were quoted in 1936 for lead carbonate ore or for zinc silicate. At flat rates the average price received by sellers was \$35.70 a ton for lead carbonate and \$17.33 for zinc silicate. There was an active demand for milled zinc silicate, but the production remained small (641 tons in 1936), and few new properties that recovered such ore were opened.

The foregoing quoted prices apply to all mines in the Tri-State or Joplin region of Kansas, Missouri, and Oklahoma.

There was considerable drilling in southwestern Missouri in 1936, and leasing was active during the latter part of the year. Old mining lands were purchased and held pending expected advances in the prices of lead and zinc. Activity was pronounced in the Oronogo, north Webb City, Carthage, Spurgeon, Racine, and Waco camps. Little work, other than drilling, was done at Aurora, Granby, Spring City, Alba, Neck City, or Duenweg. Nearly all the crude ore produced was mined near Carthage, Waco, and Oronogo, and most of the zinc tailings treated came from near Joplin. About 75 percent of the lead was from the Oronogo camp, which also produced more than 22,000 tons of sphalerite from crude ore shipped to the Central mill of the Eagle-Picher Mining & Smelting Co. in Oklahoma.

The estimated flotation product from ore mined in southwestern Missouri in 1936 was 20,270 tons of sphalerite and 500 tons of galena. Flotation sphalerite concentrates from Missouri ores in 1935 were only 4,520 tons. The mills in southeastern Missouri made 64,671 tons of flotation galena concentrates in 1936 and 53,488 tons in 1935.

Of about 427,000 tons of sphalerite shipped from the Tri-State region, it is estimated that the flotation concentrates amounted to 198,826 tons in 1936 compared with 159,000 tons in 1935. Since the extension of flotation the average grade of the galena concentrates has declined several points, whereas that of the sphalerite has increased slightly. Some of the galena from the jigs and tables has a lead content of 80 percent (and above), but the flotation galena probably does not average more than 70 percent. The small quantity of galena produced at tailing mills is of low grade, averaging from 48 to 70 percent. About 50 mines, large and small, were worked in southwestern Missouri in 1936; only 10 mills were operated, and the greater part of the ore mined was treated in Oklahoma.

The largest shippers of sphalerite concentrates in 1936 were as follows: Missouri Mining Co., operating a large tailing plant at Chitwood; D. & C. Mining Co. and Denny Mining Co. at Carthage; Playter Mining Co. at Waco; Spurgeon Mining Co. at Spurgeon; and the Burton Mining Co. near Joplin. The Oronogo Mutual Mining Co., Hickman Mining Co., and Webb City Lead & Zinc Co. shipped an aggregate of more than 368,000 tons of crude ore by rail to the Central mill in Oklahoma, and other properties are preparing to make shipments to that plant. The Little Phoebe Mining Co. shipped some sphalerite from Wentworth late in 1936. The largest shipper of zinc silicate was Pilant & Co. at Granby; small shipments were made from Racine and Aurora.

The old Oronogo Circle mine has been dewatered, and some ore is being stripped in the cave-in. Preparations are being made to unwater old properties at Waco, Neck City, Webb City, and Belville.

The lead ore (3,418,800 tons) mined in 1936 in the southeastern Missouri disseminated-lead district yielded 4.26 percent in galena concentrates averaging 76 percent lead. Very little galena was shipped by small gougers and prospectors. The mines and mills of the St. Joseph Lead Co. have a daily capacity of about 17,000 tons. Four mills were active in 1936. The Federal mine and mill were operated 273 days and the Leadwood, Bonne Terre, and Desloge plants about 144 days.

Oklahoma.—About 40 mills, large and small, were operating in Oklahoma at the end of 1936. There were at least 40 operators who did not mill their own crude ore but shipped it to custom concentrating plants or central mills. The Tri-State Zinc & Lead Ore Producers Association reported that at the end of the year stocks of sphalerite at mines in the Tri-State region had been reduced to 11,028 tons and those of galena to 6,808 tons. Most of these stocks were held by two or three large operators who sold substantial quantities early in 1937, so that the stocks of zinc concentrates are only a little larger than the weekly purchases.

Few companies segregate their coarse galena from the flotation galena, but it is estimated that the flotation galena produced in Oklahoma in 1936 was about 6,800 tons and the flotation sphalerite about 149,000 tons. A large part of the concentrates from the tailing mills and from the central mills is a flotation product. The tailing mills produce very small quantities of low-grade galena, and the flotation galena at the large mills treating crude ore is of lower grade than the jig and table galena; on the other hand, much of the flotation sphalerite made is of higher grade than the coarse concentrates. This

has resulted in reducing the lead content of the galena and increasing that of the sphalerite concentrates.

The capacity of some of the larger mills was increased in 1936, but few new mills to treat crude ore were built, little exploration was done, and only a few churn drills were operated by the larger companies. The number of drills operated in the Tri-State region in 1936 probably did not exceed 20; the total number had increased to 50 by April 1937. Higher prices probably will result in increased drilling in the Melrose section of the western part of the region. At many old mines the ore is coming from pillars and other clean-ups, and if present production is to be continued development must be done in 1937.

Nearly 3,180,000 tons more old tailings than crude ore were treated in Oklahoma in 1936, and the output of the tailing mills in the Tri-State region was more than 113,000 tons.

The mine shipments of lead and zinc concentrates, the recovered metal contents, and the tenor of lead and zinc ores and tailings are given for Oklahoma in the following tables:

Mine shipments of lead and zinc in Oklahoma, 1935-36

Year	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Metal content ¹			
					Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

	1,176,166	97,721,683	6,617,938	260,571,981	4,183	106,933

¹ Including Quapaw and Sunnyside.

There was no output from the Peoria camp in 1936 or 1935. The output from the old Commerce (Hattenville) camp in 1936 was about 290 tons of galena and 833 tons of sphalerite, mainly from the leases of the Commerce Mining & Royalty Co. The producers in the Quapaw-Sunnyside area were the Kansas & Oklahoma Mining Trust, Atlas Milling Co., Mission Mining & Royalty Co., Century Zinc Co. (Scott), and St. Louis Smelting & Refining Co. (No. 4). In the central and western parts of the Oklahoma portion of the Tri-State region the following mills were operated partly on ore and partly on tailings: Evans Wallower Lead Co. (No. 7), Skelton Lead & Zinc Co., and Lawyers Lead & Zinc Co. The following mills treated tailings only: Cardin Mining & Milling Co. (Nos. 1, 2, and 3), Commerce Mining & Royalty Co. (two mills), Britt Mining Co., Tri-State Zinc Co. (two mills), Youngman Milling Co. (Ritz), Andrews Mining & Milling Co. (Whitebird), Cortez King Brand Mining Co., C. Y. Semple (Huttig), and W. H. Aul Mining Co. (Howe). The Eagle-Picher Mining & Smelting Co. (Central mill) treated more crude ore than any other mill in the district; its total and that of the Bird Dog, See Sah, and Blue Goose mills of the Commerce Mining & Royalty Co. aggregated more than half of all the crude ore milled in Oklahoma in 1936. Other large outputs were made by the Evans Wallower Lead Co. (No. 4), Interstate Zinc & Lead Co. (Woodchuck), Rialto Mining & Royalty Co., United Zinc Smelting Corporation, Admiralty Zinc Co., Mary M. Mining Co., Velie Mines Corporation (Velie, Wilson, and Farmington mines), Guaranty Mining & Royalty Co., Indian Mining & Milling Co., Canadian Mining & Milling Co., Meteor Four Mine, Black Mining Co., Lavrion Mining Co., and Baxter Mining & Development Co. All the Admiralty Zinc Co. leases were purchased by the Mary M. Mining Co., and early in 1937 all the latter company's property was acquired by Eagle-Picher Mining & Smelting Co.

Some of the larger Oklahoma shippers to the Central mill of the Eagle-Picher company were the Davis Big Chief Mining Co., Craig Mining Co., Cameron & Henderson, Blue Eagle Mining Co., F. H. Nesbitt, J. Dryer, W. H. Mining Co., Henderson Mining Co., and Loyce June Mining Co. The Commerce Mining & Royalty Co. milled crude ore from many of its own properties at the Bird Dog mill as well as ore received from the B. H. & W. Mining Co. (S. S. & G. and Anna Beaver mines) and other mines. The capacity of the Bird Dog mill has been increased one-third, and that of the Central mill (5,500 tons per day) is to be increased to more than 9,000 tons.

Wisconsin.—The output of both galena and sphalerite concentrates in Wisconsin increased in 1936. The grade of the raw zinc concentrates, however, was much lower than in 1935 so that the recovered zinc content declined 797 tons. Practically all the raw zinc concentrates were shipped to the roasting plant of the Vinegar Hill Zinc Co. at Cuba City.

The Vinegar Hill Zinc Co. worked the Blockhouse mine 159 days, the Mullen No. 2 mine 134 days, and the Doyle-Harty mine 235 days; it produced most of the zinc and lead concentrates. The Thomas Mining Co. worked the Crawford mine 129 days, and the Meloy & Baker Mining Co. operated the De Rocher mine 203 days. The O. H. & S. Mining Co. mine near Platteville was worked 60 days, and the Hill mine at Linden 120 days. Other producers were the Doyle & Murray Mining Co. at Shullsburg and the George Baker mine at Benton.

Small lots of concentrates were shipped from various properties, and some stocked sphalerite made prior to 1936 was shipped by the McKinlay Mining Co. of Dodgeville.

The mining and milling methods at the Doyle mine at Shullsburg are described in a recent publication of the Bureau of Mines.³

Mine production of lead and zinc in Wisconsin, 1935-36

The output of gold, silver, copper, lead, and zinc from mines in Idaho in 1936, in terms of recovered metals, was 80,291.40 fine ounces of gold, 14,537,530 fine ounces of silver, 2,954,000 pounds of copper, 182,678,000 pounds of lead, and 98,200,000 pounds of zinc. This output compares with a production in 1935 of 83,823.06 ounces of gold, 10,240,953 ounces of silver, 2,095,867 pounds of copper, 158,040,250 pounds of lead, and 62,105,568 pounds of zinc. There were 281 lode mines and 828 placers producing in 1936 compared with 289 lode mines and 1,079 placers in 1935.

Since 1863 the output of the five metals in Idaho has been as follows: Gold, 7,030,826.39 fine ounces; silver, 379,546,495 fine ounces; copper, 83,902 tons; lead, 5,021,437 tons; and zinc, 577,904 tons. The total value of this output has been \$1,053,213,440.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price²; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464 + per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ Assisted by Jeannette Froiseth.

² The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25-28.

¹ Dragline and power-shovel excavators with sluices or special amalgamators.² Figures for floating dredges include those for dry-land dredges; separate figures not available.

Gold.—The output of recoverable gold in Idaho was 80,291.40 fine ounces in 1936, a decrease of 4 percent from the output in 1935. Gold produced from lode mines amounted to 45,861.60 ounces, a decrease of 6,210.43 ounces, and gold recovered at placers amounted to 34,429.80 ounces, an increase of 2,678.77 ounces. Most of the gold from placers came from the Warren and Boise Basin districts where dredges were operated. Twelve floating (bucket) dredges recovered 26,098.19 ounces of gold in 1936 compared with nine in 1935 which recovered 23,616.96 ounces. Siliceous gold ore yielded 42,176.01

ounces of gold (53 percent of the total) in 1936, a decrease of 6,028.02 ounces; placers yielded 43 percent. Nearly 66 percent of the gold from lode and placer mines was recovered from 12 mines in Boise, Elmore, Idaho, Owyhee, and Valley Counties. The Meadow Creek mine of the Yellow Pine Co. at Stibnite was the largest producer of gold in Idaho in 1936; it was followed by the Golden Anchor mine at Burgdorf, the Wharton property (dredge) at Centerville, the Gold Hill mine at Quartzburg, the Idaho Gold Dredging Co. and the Baumhoff-Fisher Co. (dredge) at Warren, the Boise-Rochester mine at Atlanta, the Jordan Creek dredge at De Lamar, the Gnome mine near Elk City, the Moores Creek Dredging Co. at Idaho City, the Orogrande-Frisco property near Orogrande, and the Grimes Co. (dredge) at Pioneerville. The Boise-Rochester mine, the largest producer of gold in Idaho from 1932 to 1935, inclusive, was closed in June 1936 and sold to The Sawtooth Co.

Silver.—The output of recoverable silver in Idaho was 14,537,530 fine ounces in 1936, the largest output ever recorded in the State and an increase of 42 percent over the output in 1935. Idaho has been the largest producer of silver in the United States since 1933; Utah and Montana rank next. Silver ore yielded nearly 69 percent of the total silver from Idaho in 1936, lead-zinc ore 19 percent, and lead ore 11 percent. The production of silver from silver ore increased from 6,310,726 ounces in 1935 to 9,991,204 ounces in 1936; silver output from lead-zinc ore and lead ore also increased. Eleven mines produced 96 percent of the silver output of the State in 1936. The Sunshine mine, the largest producer of silver in the United States, produced nearly 63 percent of the State output; it was followed by the Hecla at Burke, Bunker Hill at Kellogg, Morning at Mullan, Crescent on Big Creek, Triumph near Ketchum, Page west of Kellogg, Star near Burke, Gold Hunter at Mullan, Clayton at Clayton, and Hewer near Lakeview in Bonner County.

Copper.—The output of recoverable copper in Idaho was 2,954,000 pounds in 1936 compared with 2,095,867 pounds in 1935, an increase of 41 percent. More than half of the copper produced in Idaho in 1936 was recovered from concentrating silver ore from the Sunshine mine on Big Creek, Shoshone County; most of the remainder was recovered from concentrating lead-zinc ore from the Bunker Hill, Morning, and Triumph mines.

Lead.—The output of recoverable lead in Idaho was 182,678,000 pounds in 1936, compared with 158,040,250 pounds in 1935, an increase of nearly 16 percent but less than the average annual output (213,324,724 pounds) for the decade 1927–36. Lead-zinc ore yielded 71 percent of the total lead in 1936, and lead ore 28 percent. Lead from lead-zinc ore increased 18,412,105 pounds and from lead ore 5,535,044 pounds. Ten mines in 1936 produced 96 percent of the total lead; the combined output of the three largest—Bunker Hill, Morning, and Hecla—was 77 percent of the total. In order of output the 10 leading producing mines were: Bunker Hill, Morning, Hecla, Page, Star, Triumph, Gold Hunter, Sidney, Clayton, and Hope; all except the Triumph, Clayton, and Hope mines are in the Coeur d'Alene region, Shoshone County. Considerable lead was also produced from the Warm Springs district in Blaine County, Bay Horse district in Custer County, Pend d'Oreille district in Bonner County, and Texas district in Lemhi County.

Zinc.—The output of recoverable zinc in Idaho in 1936 was 98,200,000 pounds, the largest ever recorded in the State and an increase of 36,094,432 pounds over the production in 1935. The unusually large gain was due chiefly to the increase in output of lead-zinc ore from the Star mine and to the resumption of operations at the Triumph mine near Ketchum, Blaine County. Substantial gains in the production of zinc were also made at the Bunker Hill, Sidney, Morning, and North Star mines. Lead-zinc ore yielded 99 percent of the total in 1936 and lead ore nearly all the remainder. There was an increase of 35,755,062 pounds in zinc from lead-zinc ore and 342,533 pounds from lead ore. Seven mines, each producing more than 2,000,000 pounds of zinc in 1936, yielded 95 percent of the total. The Morning mine of the Federal Mining & Smelting Co. continued as the largest zinc producer in Idaho, followed by the Bunker Hill, Star, Triumph, Sidney, Frisco, and Page mines.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Idaho, 1935-36, by counties, in terms of recovered metals

MINING INDUSTRY

The mining industry in Idaho improved to such an extent in 1936 that the value of the metal output rose from \$19,522,704 in 1935 to \$27,654,472 in 1936, an advance of nearly 42 percent. This large gain was due chiefly to the marked increases in the average sales prices of silver, lead, and zinc; silver from 71.875 cents an ounce in 1935 to 77.45 cents in 1936, lead from 4 to 4.6 cents a pound, and zinc from 4.4 to 5 cents a pound. As a result of increased metal prices mines in Idaho produced a record output of silver and zinc and the largest

output of lead since 1931. The output of gold decreased slightly due to the closing of the Boise-Rochester property at Atlanta, Elmore County, in June. However, the gradual yearly increase in the production of gold from bucket dredges is notable. The output of ore from mines in the Coeur d'Alene region, the chief producing area in Idaho, increased considerably, especially that of lead-zinc ore. The features of the year were the unusually large increase in production of silver from the Sunshine mine; the large increase in production of zinc from the Star, Bunker Hill, Sidney, and Morning mines; and the reopening of the Triumph lead-zinc mine near Ketchum, Blaine County. The smelter and refinery of the Bunker Hill & Sullivan Mining & Concentrating Co. were active throughout the year at an increased rate, and the electrolytic zinc plant of the Sullivan Mining Co. was worked at capacity. The Sullivan Mining Co. is planning to increase the capacity of the plant from 60 to 90 tons a day.

ORE CLASSIFICATION

Ore sold or treated in Idaho, 1935-36, with content in terms of recovered metals

Gold ore.—The output of gold ore in Idaho was 264,446 tons (including old tailings) from 171 properties in 1936 compared with 262,202 tons from 180 properties in 1935; it represented nearly 15 percent of the total output of ore in the State in 1936. More than 76 percent of the total gold ore (and old tailings) was produced from the Orogrande-Frisco property near Orogrande, Yellow Pine property at Stibnite, Gold Hill mine at Quartzburg, and Boise-Rochester mine at Atlanta.

Gold and silver ore.—The output of 427 tons of gold and silver ore in Idaho in 1936 came chiefly from the Come-Back mine in Boise County and the Wilson mine in Owyhee County.

Silver ore.—Thirty mines produced 250,265 tons of silver ore in 1936 compared with 15 mines producing 181,367 tons in 1935. More than 97 percent of the total came from the Sunshine and Crescent mines in Shoshone County and the Hewer property in Bonner County.

Copper ore.—A little copper ore (284 tons) was produced from eight mines in Idaho in 1936; the output in 1935 was 243 tons.

Lead ore.—The output of lead ore was 305,967 tons from 53 properties in 1936 compared with 256,077 tons from 56 properties in 1935. Nearly 98 percent of the total came from the Hecla and Gold Hunter mines in the Coeur d'Alene region, the Clayton mine in the Bay Horse district, and the Hope property in the Pend d'Oreille district.

Lead-zinc ore.—The output of lead-zinc ore (including old tailings) was 986,141 tons from 19 properties in 1936 compared with 820,674 tons from 12 properties in 1935. Except for a small lot of ore from Camas County, all lead-zinc ore (and old tailings) produced in 1936

came from 13 mines in Shoshone County and 5 mines in Blaine County and was treated by flotation. It represented more than 54 percent of the total ore. The Bunker Hill property continued to be the leading producer of lead-zinc ore, followed by the Morning, Star, Page, Frisco, Triumph, and Sidney.

METALLURGIC INDUSTRY

The 1,807,530 tons of ore (including old tailings) produced in 1936 in Idaho comprised 196,011 tons (10.85 percent) treated at gold and silver mills, 1,583,287 tons (87.59 percent) treated at concentration plants, and 28,232 tons (1.56 percent) shipped crude to smelters.

Of the ore (and old tailings) treated at gold and silver mills, 50,713 tons were treated at straight amalgamation plants, 46,657 tons were treated by combined amalgamation and concentration, and 98,641 tons (including 2,700 tons of old tailings) were treated at straight cyanidation plants. In 1935, 41,017 tons of ore (and old tailings) were treated by amalgamation, 91,480 tons by combined amalgamation and concentration, and 51,504 tons by cyanidation. Nearly 82 percent of the ore treated by amalgamation in 1936 came from mines in the Boise Basin district; 96 percent of the ore treated by amalgamation and concentration came from mines in the Middle Boise, Marshall Lake, McDevitt, and Warren districts; and 96 percent of the ore and old tailings treated by cyanidation came from mines in the Orogrande district.

Ore and old tailings treated at straight concentration plants increased from 1,315,585 tons in 1935 to 1,583,287 tons in 1936. Siliceous material treated at concentration plants increased from 255,021 to 309,547 tons; lead ore from 239,896 to 287,571 tons; and lead-zinc ore and old tailings from 820,654 to 986,141 tons. A little copper ore was also treated by concentration.

* Included under "Undistributed."

† Exclusive of lode output, which is included under "Undistributed."

‡ Includes items entered as "r" and "g" above.

ADA COUNTY

Nearly all the output in Ada County in both 1935 and 1936 was placer gold recovered from sand and gravel from the Snake River and Highland (Boise River) districts; production in 1936 was considerably more than in 1935 due to the operation of a power shovel and dragline by the Gold Flour Mining Co. on the north bank of the Snake River adjacent to Grand View.

ADAMS COUNTY

Seven Devils district.—The output of metals from the Seven Devils district has been comparatively small for several years, but in 1935 the district became an important producer of gold due to the discovery of high-grade gold ore at the Placer Basin property 40 miles northwest of Council. The property continued to produce rich gold ore in 1936, and besides 318 tons of ore shipped to a smelter, about 600 tons of ore were milled in a 25-ton cyanidation plant.

BLAINE COUNTY

Little Wood River district.—No ore was produced in the Little Wood River district in 1935; in 1936 several cars of lead-zinc ore from an ore dump near Muldoon were shipped to Midvale, Utah, for milling.

Mineral Hill district.—The total value of the metal output of the Mineral Hill district in 1936 was slightly less than in 1935. The chief output in both years was gold ore of smelting grade from the Happy Day, Golden Bell, and Lindy properties.

Vienna district.—The Vienna mine was leased to the Kimball Mining Syndicate in 1935, and 375 tons of silver ore were concentrated by flotation; besides silver the concentrates contained considerable gold and a little lead and copper. The property was idle in 1936.

Warm Springs district.—The value of the metal output of the Warm Springs district increased from \$10,654 in 1935 to \$994,818 in 1936 as a result of the operations of the Triumph, North Star, and West Shore mines. The properties were idle in 1934 and 1935, but the Hailey Triumph Mines Co. started operations in January 1936 and shipped about 38,000 tons of zinc-lead ore to Bauer and International, Utah, for milling. The Triumph mine, a large producer of silver, lead, and zinc from 1927 to 1930, was the largest producer in the county in 1936. The only output in 1935 worth mentioning was a little zinc-lead ore from waste dumps.

BOISE COUNTY

Boise Basin district (Centerville, Placerville, Idaho City, Pioneer-ville).—The Boise Basin district was the chief gold-producing area in Idaho in 1936, as the output from placer mines increased from 4,981.54 ounces in 1935 to 12,335.80 ounces in 1936; the output from lode mines in 1936 was 8,814.80 ounces, an increase of 967.40 ounces over 1935. The large increase in production from placer properties was due chiefly to the gain in gold recovered by floating bucket dredges. Two floating dredges were constructed in 1935, one by The Grimes Co. and the other by the Fisher-Baumhoff Co. (Wharton placer.) The Fisher-Baumhoff Co. constructed another floating dredge in 1936, and the Moores Creek Dredging Co. also constructed a floating dredge. The output of gold from the four dredges in 1936 was 11,020.46

ounces compared with 3,508.64 ounces from two dredges in 1935. Considerable gold was also recovered in both 1935 and 1936 by sluicing at the Gold Hill Placers. The Talache Mines, Inc., by far the largest producer of gold ore in the county, increased its output from 31,181 tons in 1935 to 39,387 tons in 1936; the ore was treated by amalgamation. The Come-Back Mining Co., an important producer of high-grade gold and silver ore in 1935, continued to ship high-grade ore in 1936.

Summit Flat district.—Operators of the Golden Cycle, Rock Creek, and Jessie properties east of Pioneerville produced 381 ounces of gold and 217 ounces of silver, a large increase over the output in 1935.

BONNER COUNTY

The largest output in Bonner County in both 1935 and 1936 was lead-silver ore from the Hope (Elsie K.) mine in the Pend d'Oreille district treated by flotation-concentration; the output in 1936 (about 10,000 tons) was more than double that in 1935. The old Hewer property in the Lakeview district was reopened in July 1935 by the Revlis Co., and several thousand tons of silver ore were treated by flotation-concentration. The mine continued to produce silver ore until July 1936, when it was closed.

BONNEVILLE COUNTY

The value of the metal production of Bonneville County was virtually the same in both 1935 and 1936; the entire output was placer gold and silver from the Mt. Pisgah district, chiefly from the McCoy Creek and Idaho Consolidated properties.

BOUNDARY COUNTY

The Idaho Continental mine in the Port Hill district continued to produce a little high-grade lead ore in both 1935 and 1936.

CAMAS COUNTY

The Little Smoky Dredging Co., operating a bucket dredge on Little Smoky Creek, was the largest producer of gold in Camas County in both 1935 and 1936, but its output of gold in 1936 was less than half that in 1935. The output of gold from lode mines in the county also decreased, as less gold ore was produced from the El Oro mine near Fairfield in the Skeleton Creek district.

CLEARWATER COUNTY

The Pierce district was the only important producing district in Clearwater County in both 1935 and 1936. Almost the entire output was placer gold, chiefly from dredging operations on Rhodes Creek. The Gold Dredging, Inc., operated its bucket dredge on Rhodes Creek both years, but the output of gold in 1936 was about 500 ounces less than in 1935. A new bucket dredge was worked in 1936 on Orofino Creek, Pierce district, by the Gold Creek Placer Co., but the gold production was not large as the company started operations late in the year.

CUSTER COUNTY

Alder Creek district.—The output of the Alder Creek district increased slightly in 1936 over 1935 as a result of the increase in output of lead-silver ore from the Bluebird mine 4 miles southwest of Mackay.

Bay Horse district.—The value of the metal output of the Bay Horse district increased from \$55,876 in 1935 to \$151,634 in 1936, due to the large increase in output of lead-silver ore from the property of the Clayton Silver Mines at Clayton. Nearly 25,000 tons of silver-lead ore were treated in 1936 in the company 50-ton flotation-concentration mill. The Ramshorn mine was also a fairly large producer of silver-lead ore in both years.

ELMORE COUNTY

Bear Creek district.—The output of gold in the Bear Creek district in 1936 was much less than that in 1935, as the Canada Gold Mines, Inc., the chief producer in 1935, was idle in 1936.

Middle Boise district.—The value of the metal output of the Middle Boise district decreased considerably—from \$737,204 in 1935 to \$164,431 in 1936—due to the closing of the Boise-Rochester mine in June 1936; the mine was the largest producer of gold in Idaho from 1932 to 1935, inclusive. While the property was operated in 1936, more than 29,000 tons of gold ore were treated by amalgamation and flotation-concentration compared with 78,036 tons of ore and old tailings treated in 1935. The Last Chance Mining Co., a new company operating property at Atlanta in 1936, was also a fairly large producer of gold. Considerable gold was recovered in both 1935 and 1936 by various placer operators along the Middle Fork of the Boise River and at King Hill on the Snake River.

Yankee Fork district.—The production of gold and silver in the Yankee Fork district in 1936 was more than in 1935 due to the increase in output of gold ore from the Bachelor Mountain and Peak claims and to the output of silver ore from the Yankee Fork mine. Most of the output in 1935 was old tailings (gold) from the Sunbeam dump treated by cyanidation and concentration; the property was idle in 1936.

GEM COUNTY

The value of the metal output of Gem County increased from \$2,268 in 1935 to \$6,599 in 1936 as a result of the increase in production of gold ore from the Black Rock mine and placer gold from the Gattfield property, both in the West View district.

IDAHO COUNTY

Camp Howard (Salmon River) district (White Bird).—The output of gold recovered from various bars along the Salmon River from Riggins to beyond Rice Creek increased from 611.00 ounces in 1935 to 865.20 ounces in 1936. In 1936 the Horseshoe Bend Bar near the mouth of Slate Creek, operated by a power shovel and dragline, was by far the most important producer in the district.

Dixie district.—The value of the metal output of the Dixie district increased from \$15,334 in 1935 to \$52,569 in 1936 due chiefly to the large increase in the output of gold from the Dixie Placers. The company was organized in April 1935 to work placer claims on Crooked

Creek, a tributary of Salmon River, and in 1936 a dragline with trommel washing plant handled 192,000 cubic yards of gravel. The output of gold from lode mines also increased as several hundred tons of gold ore from the Dixie Comstock property were treated by flotation-concentration.

Elk City district.—The production of gold in the Elk City district increased from 865.46 ounces in 1935 to 1,263.80 ounces in 1936 due chiefly to increases in output of placer gold from the Deadwood claim and lode gold from the Black Lady (Pilot Knob Gold Corporation) mine. The Mount Vernon Co., operating a bucket dredge at the Deadwood property, was by far the largest producer of gold in the district in both 1935 and 1936. Considerable gold was also recovered in both 1935 and 1936 from placer operations at the Columbus, Gold Hill & American Hill, and Little Million properties. The only important lode producer in the district in 1936 was the Pilot Knob Gold Corporation; the company constructed a new 25-ton cyanide mill and treated about 900 tons of gold ore.

Florence district.—There were several placer and lode operators in the Florence district in 1935 and 1936, but the chief source of gold in both years was sluicing operations at the Homestake Placers.

Lower Salmon River district.—The entire output of the Lower Salmon River district in 1935 and 1936 was placer gold, chiefly from many transient operators near Keuterville and Boles. Most of the output in both years came from the Hatke claim near Keuterville.

Marshall Lake district (Burgdorf).—The value of the metal output of the Marshall Lake district increased from \$64,247 in 1935 to \$261,345 in 1936 as a result of the large increase in output of gold ore from the Golden Anchor (Holte) mine. The Golden Anchor Mining Co. constructed a 50-ton amalgamation and flotation plant during the summer of 1935 and became an important producer of gold. In 1936 it was the largest producer of gold in the county and ranked second among the gold producers of the State. The Walker-Wilcox group, a fairly large producer of gold ore in 1934 and 1935, was idle in 1936.

Newsome district.—The chief output in both 1935 and 1936 was low-grade gold ore from the Imogene mine treated by amalgamation.

Orogrande district.—The value of the metal output of the Orogrande district in 1936 was \$183,468 compared with \$113,976 in 1935. Most of the output in 1935 and 1936 was gold ore from the Orogrande-Frisco and Gnome properties treated by cyanidation; there was a substantial increase in the production of gold from each property in 1936. Low-grade gold ore (90,000 tons) from the Orogrande-Frisco property was mined by steam shovel from open-cuts and treated in a 500-ton cyanide plant. The Homestake mine operated by the Penman Mines Corporation was also a large producer of gold ore in 1935, but its output decreased considerably in 1936. More placer gold was produced in the district in 1936 than in previous years; most of it came from the Baker Gulch and Triangle claims.

Robbins (Buffalo Hump) district.—The production of gold from the Robbins district in 1936 was slightly less than that in 1935, as the output of gold ore from the War Eagle property was less. A large part of the output in both years was old tailings (gold) from the Jumbo dump treated by cyanidation.

Salmon River district.—Considerable placer gold was recovered by various operators in both 1935 and 1936 along the main Salmon River between Riggins and Proctor Creek.

Simpson (Salmon River) district (Lucile).—The value of gold output of the Simpson district in 1936 was about half that in 1935 as the McKinley mine, an important producer of lode gold in 1935, was idle in 1936; the output of placer gold was much less than in 1935.

Ten Mile district (Golden).—The Lone Pine mine was, as usual, the largest producer of ore in the Ten Mile district, but its output in 1936 was less than in 1935, consequently the total value of the metal output of the district was less. The mine produced 4,643 tons of gold ore in 1936 compared with 5,512 tons in 1935. The Shamrock mine was also an important producer of gold ore in both 1935 and 1936, and the Black Bird mine became an important producer in 1936. There were several placer operators in the district in both 1935 and 1936, but the chief production came from the Key claim.

Warren district.—The output of gold from the Warren district decreased from 16,143.06 ounces in 1935 to 10,239.40 ounces in 1936 due to the closing in December 1935 of the floating bucket dredge operated by the Warren Creek Dredging Co. and the large decline in production of gold from the two floating bucket dredges operated by the Idaho Gold Dredging Co. The Baumhoff-Fisher Co., a new producer in the district in 1936, operated a floating bucket dredge on Steamboat Creek; the combined output of gold from the three dredges in 1936 was about 9,300 ounces compared with 15,565 ounces in 1935. A fair amount of placer gold was also produced in both 1935 and 1936 from the Golden Rule claim. The production of gold from lode mines in the district increased considerably in 1936 owing to the large increase in output of gold ore from the Little Giant property operated by the Unity Gold Production Co. The property was operated throughout the year, and about 3,500 tons of gold ore were treated by amalgamation and concentration.

JEROME COUNTY

The entire metal output of Jerome County in both 1935 and 1936 was placer gold and silver recovered from various bars along the Snake River. The production of gold in 1936 was nearly double that in 1935.

LATAH COUNTY

The entire metal output of Latah County in both 1935 and 1936 was placer gold and silver from claims in the Gold Creek, Hoodoo, and Moscow Mountain districts. The chief producer in 1935 was the Rex claim and in 1936 the Annie Marie claim, both in the Hoodoo district.

LEMHI COUNTY

Blackbird district.—The Meadow mine near Forney was the only producer in the Blackbird district in 1935 and 1936; the output of high-grade gold ore was less in 1936 than in 1935.

Blue Wing district.—All the output of the Blue Wing district in both 1935 and 1936 was tungsten-silver-copper ore from the Ima property 15 miles northeast of May, treated in a 100-ton flotation-concentration plant.

Eureka district.—Nearly all the output of the Eureka district in both 1935 and 1936 was placer gold, chiefly from the McNutt claim.

Gibbonsville district.—The total value of the metal output of the Gibbonsville district increased from \$8,752 in 1935 to \$44,970 in 1936, due chiefly to the treatment of several thousand tons of gold ore in a 50-ton flotation-concentration plant by the Gold Producers, Inc. The company constructed the plant late in 1935 to treat custom ore from various mines in the county, but nearly all the ore treated in 1936 came from properties in the Gibbonsville district. The Clara Morris property was an important producer of high-grade gold ore in 1935 and 1936, and the Sundown placer claim became an important producer of gold in 1936 under the operation of the North Fork Placers Co.

Indian Creek district.—The output of gold in the Indian Creek district in 1936 was more than three times that in 1935, as there was a large increase in the production of gold ore from the Kittie Burton & Ulysses group. The Indian Creek Mining Co., Inc., operated the property throughout the year and treated several thousand tons of gold ore by flotation-concentration.

Junction district.—The output of silver and lead increased in the Junction district in 1936 due to shipments of silver-lead ore from the Plymouth mine near Leadore.

McDevitt district.—The Copper Queen mine near Tendoy was virtually the only producer in the McDevitt district in 1935 and 1936. The mine was operated by the Tendoy Copper Queen Mining Co., and the output of gold ore (containing appreciable quantities of silver and copper) in 1936 was more than double that in 1935; about 4,000 tons of ore were treated in 1936 by amalgamation and concentration.

Mackinaw district.—The output of gold from both lode and placer mines in the Mackinaw district in 1936 was slightly less than in 1935; most of the output in both years was placer gold, chiefly from the K. G. W. and Big Jureano claims. The chief production from lode mines in 1935 was first-class lead ore from the Ringbone Cayuse mine containing considerable gold, and in 1936 the entire output from lode mines was gold ore from the Shoo Fly mine.

Mineral Hill district.—The value of the metal output of the Mineral Hill district decreased from \$55,969 in 1935 to \$44,826 in 1936. The Grunter mine, operated by the American Consolidated Mining & Milling Co., was a large producer of gold ore in 1935, but the property has been idle since August 1935, when a fire destroyed the 100-ton concentration plant. The Gold Hill Mines, Inc., constructed a new 100-ton flotation-concentration plant in 1935 and treated a few thousand tons of gold ore from the old Kentuck & Speculation groups. The company increased its output in 1936 and became the largest producer of gold in the county.

Pratt and Sandy Creeks district.—The Gem mine on Sandy Creek was an important producer of gold ore in 1936; the output of ore in the district in 1935 was small.

Salmon River district.—Many placer operators worked bars along the Salmon River west of Salmon in 1936, and the total value of the gold output was about \$3,200 in 1936 compared with \$5,462 in 1935.

Texas district.—The value of the metal output of the Texas district increased from \$14,082 in 1935 to \$54,275 in 1936 as a result of the

large increase in shipments of lead-silver ore from the Latest Out mine near Gilmore.

Yellow Jacket district.—The increase in the output of gold in the Yellow Jacket district in 1936 was due chiefly to the treatment of low-grade gold ore from the Yellow Jacket mine near Forney by flotation-concentration. Placer gold recovered from Yellow Jacket Creek was valued at \$1,176.

NEZ PERCE COUNTY

Most of the output in Nez Perce County in both 1935 and 1936 was placer gold recovered from various bars along the Snake River.

OWYHEE COUNTY

Carson district (Silver City, De Lamar).—The value of the metal output of the Carson district increased from \$53,800 in 1935 to \$126,043 in 1936 as a result of the operation of a bucket dredge on Jordan Creek near De Lamar by the Jordan Creek Placers. The dredge started operating July 25, 1935, and its output of gold in 1936 was more than double that in 1935. The output of gold from lode mines increased from 149.80 to 326.80 ounces. There were 17 lode mines producing in the district in 1936, but only 2 were important producers—the Ida Bell (Idaho Exploration, Inc.) and Potosi mines, both producers of gold ore.

Castle Creek district.—Several small lots of exceptionally rich silver ore were produced from the Castle Creek district in both 1935 and 1936.

Snake River district.—Placer gold recovered from claims along the Snake River in Owyhee County was valued at \$18,382 in 1936 compared with \$22,496 in 1935. The largest producer in both years was the Valley Pride property at Grand View, but its output of gold in 1936 was only half that in 1935.

POWER COUNTY

The total value of placer gold and silver recovered from various claims along the Snake River near American Falls was \$1,795 in 1936 compared with \$2,581 in 1935.

SHOSHONE COUNTY

COEUR D'ALENE REGION

Mine production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region, Shoshone County, Idaho, 1935-36, and total, 1884-1936, in terms of recovered metals

Year	Lode mines	Placers	Ore	Gold	Silver	Copper	Lead	Zinc	Total value
			<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>

¹ Figures not available.

² Short tons.

The Coeur d'Alene region has been the largest producing area in Idaho for many years. In 1936 mines in this region produced more than 80 percent of the total ore output of the State, 94 percent of the silver, 89 percent of the copper, 95 percent of the lead, and 90 percent of the zinc. More than 65 percent of the total ore produced from mines in the region in 1936 was lead-zinc ore, 18 percent was lead ore, and 16 percent was silver ore.

Beaver district.—Only 21 tons of ore were produced in the Beaver district in 1935, but in 1936 about 13,000 tons of zinc-lead ore from old waste dumps of the Interstate-Callahan property were treated in the Galena flotation plant. The remainder of the district output was placer gold and silver chiefly from Potosi Gulch.

Coeur d'Alene district.—Placer gold recovered by drift mining at old claims owned by the Coeur d'Alene Placer Co. was valued at \$7,127 in 1936 compared with \$9,933 in 1935; the chief producers in both years were the Nugget Gulch Leasing Co. and the Beehive Bar.

Eagle district.—The Jack Waite mine, a large producer of lead-zinc ore, lies in both Shoshone County, Idaho, and Sanders County, Mont. The entire production in both 1934 and 1935 came from Sanders County, but in 1936 part of the output (about 4,000 tons) came from the Eagle district in Shoshone County, and as a result the district again became a large producer of zinc and lead.

Evolution district.—The total value of the metal output of the Evolution district in 1936 was \$7,259,068, the largest of any district in Idaho; in 1935 the total value was \$4,339,518. The entire output in both 1935 and 1936, except a little silver ore from the Polaris mine in 1936, was silver ore from the Sunshine mine concentrated by flotation. The mine and mill were operated continuously, and 215,949 tons of ore were treated in 1936 compared with 160,417 tons in 1935. The concentrates in 1936 contained 9,103,113 ounces of silver, as well as some gold, copper, and lead, an unusually large increase over the 5,876,910 ounces of silver contained in concentrates in 1935. The property continued to be the largest producer of silver in the United States.

Hunter district (Mullan).—The output of all metals in the Hunter district increased decidedly in 1936 over 1935 as a result of the increase in output of lead-zinc ore from the Star and Morning mines. The Star mine, idle in 1934, was reopened on a production basis late in 1935 and continued producing at a limited rate throughout 1936; about 116,500 tons of ore containing chiefly zinc and lead were treated in the Hercules flotation plant. The Morning mine, as usual, was the most important producer in the district and the largest producer of zinc in the State. The mine and 1,200-ton flotation-concentration mill were operated continuously on a 5-day-week basis, and 313,866 tons of lead-zinc ore were treated. Lessees continued to operate the Gold Hunter mine, and the output of silver and lead was considerably more in 1936 than in 1935; about 46,000 tons of lead-silver ore were treated in 1936 in a 500-ton flotation plant. The output of zinc-lead ore from the Golconda mine decreased decidedly—from 17,643 tons in 1935 to about 6,000 tons in 1936; the property was operated under lease in 1936 by the Trinum Co.

Lelande district (Burke, Mace, Frisco).—The value of the metal output of the Lelande district increased from \$2,863,762 in 1935 to \$3,357,865 in 1936 owing chiefly to the increase in output of silver and

lead from the Hecla mine. The Hecla Mining Co. operated its mine and mill continuously on a 5-day-week basis, shipped 13,135 tons of first-class silver-lead ore to a smelter, and treated 204,839 tons of similar ore by gravity- and flotation-concentration. The mine ranked second in the production of silver in the State and third in lead. The next important producer in the district in both 1935 and 1936 was the Frisco mine, operated under lease by the Hull Leasing Co.; several thousand tons of zinc-lead ore were treated by flotation-concentration, and the production of zinc and lead in 1936 was much more than that in 1935. Almost all the remainder of the district output in both 1935 and 1936 was old tailings from Canyon Creek containing chiefly zinc.

Placer Center district.—The chief output of the Placer Center district in both 1935 and 1936 was lead-silver ore from the Dayrock mine operated by lessees.

St. Joe district.—Placer gold recovered from claims in the St. Joe district was valued at \$2,226 in 1936 compared with \$1,547 in 1935; nearly all the output in both years came from the Gold Producer claim on Bostonian Creek.

Summit district (Murray).—The Idaho Mother Lode Gold Mines, Inc., was the only lode producer in the Summit district in 1935 and 1936, and the production of gold in each year was about the same. Several placer operators in the district in both 1935 and 1936 recovered considerable gold from various claims owned by the Coeur d'Alene Placer Co.

Yreka district (Kellogg).—The total value of the metal output of the Yreka district increased from \$4,723,376 in 1935 to \$6,360,921 in 1936, due chiefly to the increase in production of lead and zinc from the Bunker Hill, Page, and Sidney mines and silver from the Crescent mine. The Bunker Hill property was, as usual, the most important producer in the district and the largest producer of lead in the State; its production of zinc has been increasing each year since 1931. The property was operated continuously in both 1935 and 1936 on a 5-day-week basis, and 348,463 tons of lead-zinc ore were treated in 1936 in concentration plants—part by flotation and part by gravity-concentration and flotation. The Page mine, operated by the Federal Mining & Smelting Co., was the next important producer in the district; its output of lead-zinc ore increased from 58,972 tons in 1935 to 71,100 tons in 1936. The output of the Crescent mine in 1936 was 16,788 tons of silver ore treated by flotation and 2,053 tons of high-grade silver ore smelted; its production of silver was about double that in 1935. The Sidney Leasing Co. operated the Sidney mine throughout the year and 25,618 tons of zinc-lead ore were treated in the Sweeny custom mill; the mine was reopened in October 1935 after being idle for 3 years. The remainder of the district output in 1935 and 1936 was chiefly lead-zinc ore from the Blackhawk mine and silver ore from the Caledonia mine.

TWIN FALLS COUNTY

The entire metal output of Twin Falls County in both 1935 and 1936 was placer gold and silver recovered from various bars along the Snake River near Twin Falls, Kimberly, and Hansen. The value of the output decreased from \$4,394 in 1935 to \$3,140 in 1936.

VALLEY COUNTY

Big Creek (Edwardsburg) district.—Nearly all the output in the Big Creek district in 1935 was gold ore from the Snow Shoe mine treated by amalgamation and concentration; most of the output in 1936 was placer gold recovered from the Smith Creek property.

Pistol Creek district.—The Pistol Creek district became a new producing area in Idaho in 1935 through the discovery of lead ore, rich in gold and silver, at the Lucky Boy mine 15 miles east of Landmark; a few cars of ore were shipped to a smelter in Utah. The property continued to produce in 1936, but the output was much less. The chief output of the district in 1936 was high-grade gold ore from the Cougar group.

Thunder Mountain district.—The Sunnyside mine at Stibnite, the only lode producer in the Thunder Mountain district, was sold late in 1935 to the Thunder Mountain Mining & Milling Co. The property was operated in 1935 by the Sunnyside Mining & Milling Co., which treated 2,340 tons of gold ore by amalgamation and concentration. The output in 1936 was much less than that in 1935. Nearly half the gold produced in the district in 1936 was recovered from placer claims.

Yellow Pine district.—The output of ore and the production of gold in the Yellow Pine district in 1936 were less than in 1935, as there was a decline in the production of ore from the Meadow Creek property, virtually the only producer in the district. The Yellow Pine Co. operated the property continuously in both years, and several thousand tons of ore containing chiefly gold and antimony were treated in a 200-ton flotation-concentration plant; the resulting concentrates, including antimony, were shipped to a smelter in Utah.

WASHINGTON COUNTY

Nearly all the metal output of Washington County in both 1935 and 1936 was first-class silver ore from the Silver Still property near Mineral in the Washington district. The Silver Still Mining Co. operated the mine throughout both years; the output of ore and its metal content in 1936 were about the same as in 1935.

The output of gold, silver, copper, lead, and zinc from Montana ores and gravels in 1936, in terms of recovered metals, was estimated at 181,100.00 fine ounces of gold, 11,585,600 fine ounces of silver, 219,104,000 pounds of copper, 38,238,000 pounds of lead, and 99,246,000 pounds of zinc. These figures are subject to revision after compilation of the final tabulations. This output compared with a production in 1935 of 151,088.03 fine ounces of gold, 9,322,951 fine ounces of silver, 154,957,470 pounds of copper, 31,177,525 pounds of lead, and 109,561,477 pounds of zinc. There were 681 lode mines and 551 placers operating in Montana in 1935; in 1936 the number of operating lode mines was about the same as in 1935, but the number of placers decreased.

From 1904 to 1935, inclusive, the total output from Montana mines was as follows: Ore, 141,355,586 short tons; gold, 4,102,697.68 fine ounces; silver, 353,669,643 fine ounces; copper, 7,353,415,798 pounds; lead, 626,001,773 pounds; and zinc, 2,907,683,034 pounds. The total value of the output from 1904 to 1935, inclusive, is \$1,756,196,983; the value of the 1936 output is estimated at \$42,190,363, and the total value of the output from 1862 to 1936 is estimated at \$2,897,407,045.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price ²; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ Figures for 1936 are preliminary; detailed data with final revisions will be released later.

² The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25-28.

Gold.—The output of recoverable gold from mines in Montana in 1936 was about 181,100.00 fine ounces compared with 151,088.03 in 1935 and 97,445.95 in 1934. Placer mines produced about 40,800.00 fine ounces of gold in 1936 compared with 26,299.23 in 1935, an increase of about 14,500 ounces, and gold mines increased about

15,500 ounces. Nearly all the increase in gold from placer mines in 1936 was from two dredges that started operations in 1935 and ran continuously during 1936—the floating dredge of Porter Bros. Corporation at Helena, which started operations in November 1935, and the dry-land dredge of Humphreys Gold Corporation at Virginia City. The floating dredge at Pioneer operated regularly in 1936, and its output of gold was about the same as in 1935; other operations included the Winston Bros. Co. plant on Prickly Pear Creek near Clancy and the Eldorado plant in Washington Gulch, Powell County. Small-scale placer operators produced about 4,500 ounces of gold in 1936, about the same as in 1935. Gold from lode mines increased from 124,789 ounces in 1935 to about 140,300 in 1936. Gold from copper ores and lead-zinc ores from Butte properties of the Anaconda Copper Mining Co. was more than double that in 1935, and there was a substantial increase at the Ruby Gulch property in Phillips County. Other large producers of gold in 1936 included the Gould, Spring Hill, Little Ben, Golden Messenger, and Comet mines, each of which produced more than 5,000 ounces of gold.

Silver.—The output of recoverable silver increased from 9,322,951 ounces in 1935 to about 11,585,600 in 1936. Nearly 68 percent of the silver came from copper ores and lead-zinc ores from the Butte district, most of which was produced by the Anaconda Copper Mining Co. Other large silver producers included the Trout, Comet, Flathead, and Granite Bimetallic mines. (Lead-zinc ore was the product of the Trout and Comet mines; siliceous silver ore was the product of the Flathead and Granite Bimetallic mines.) The Lone Pine & Argyle Silver mine in the Vipond district, Beaverhead County, was also an important silver producer in 1936.

Copper.—The Anaconda Copper Mining Co. at Butte as usual produced nearly all the State output of copper, which increased from 154,957,470 pounds, in terms of recoverable metal, in 1935 to about 219,104,000 pounds in 1936. In addition to the usual mining, milling, and smelting operations on copper ores, the Anaconda Copper Mining Co. reopened the sand-leaching plant at Anaconda and re-treated nearly 550,000 tons of old copper tailings by a combination of acid-leaching and flotation. Nearly all the remainder of the copper came from lead-zinc ores. Copper was by far the most important mineral product of Montana in 1936.

Lead.—The output of recoverable lead in 1936 was about 38,238,000 pounds compared with 31,177,525 in 1935. Lead-zinc ore from the Orphan Girl and Emma mines at Butte (operated by the Anaconda Copper Mining Co.) and the Jack Waite, Comet, and Trout mines yielded about 85 percent of the total output. Ore from these mines was treated at four selective flotation plants. The slag-fuming plant at East Helena, also operated by the Anaconda Copper Mining Co., was an important producer of lead in a zinc-lead fume sent to the Great Falls zinc-reduction plant.

Zinc.—The recoverable output of zinc decreased about 9 percent—from 109,561,477 pounds in 1935 to about 99,246,000 in 1936. About 67 percent of this zinc came from the Orphan Girl and Emma mines at Butte. Other important producers of zinc in 1936 were the Trout, Comet, and Josephine mines and the slag-fuming plant at East Helena. The Anaconda Copper Mining Co. operated the Orphan Girl and Emma mines and the slag plant at East Helena while the Josephine mine was operated by lessees from the company.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Montana in 1935, by counties, in terms of recovered metals

MINING INDUSTRY

The marked increase in output of copper in both 1935 and 1936 was of especial interest to the mining industry in Montana. The output of copper ore from Butte has increased gradually since 1934, and the copper department of the Anaconda Copper Mining Co. was operating at near capacity at the end of 1936. The copper output in 1936 (219,104,000 pounds) was considerably larger than the average annual output (173,787,409 pounds) for the decade 1927-36. The increase in value of copper produced in 1936 compared with 1935 accounted for 65 percent of the total increase in value of State output of all five metals. There were also substantial increases in value of gold and silver produced, and copper ore was also responsible for most of these gains.

Activity continued at properties producing gold ore in 1936. New cyanide mills were constructed at the Ruby Gulch mine in Phillips County, and two new cyanide plants were built at properties near Argenta in Beaverhead County; gold mills at several other properties were reconditioned and enlarged.

ORE CLASSIFICATION

Ore sold or treated in Montana in 1935, with content in terms of recovered metals

Gold ore.—The output of gold ore in Montana in 1935 was 437,467 tons, a marked increase from 243,405 tons in 1934. Most of the increase was in ore to gold and silver mills, but there was a substantial increase in gold ore smelted. Of the total gold ore produced in 1935, 232,860 tons were treated at gold and silver mills, 147,048 tons were concentrated, and 56,489 tons were smelted. Mines in Lewis and Clark, Madison, and Park Counties produced about 60 percent of the total gold ore in 1935.

Gold and silver ore.—The output of gold and silver ore increased 31,158 tons in 1935; most of it came from the Emery mine in Powell County and the Jib mine in Jefferson County. About 75 percent of it was milled, and the rest was smelted.

Silver ore.—The output of silver ore more than doubled in Montana in 1935. Most of it came from the Granite Bimetallic and Combination mines in Granite County, the Flathead mine in Flathead County, and the Lone Pine & Argyle Silver mine in Beaverhead County. More than half the silver ore was milled; the rest was smelted.

Copper ore.—The output of copper ore in 1935 was nearly three times larger than that in 1934; as in the past, nearly all of it came from the Butte properties of the Anaconda Copper Mining Co., and most of it was treated by flotation concentration. Metals recovered from copper ore (including the value of copper in precipitates) were valued at \$15,916,310, or about 51 percent of the total value of the State output.

Lead ore.—There were no large producers of lead ore in Montana in 1935, and the output was slightly less than that in 1934; most of the 1935 output was milled.

Zinc ore.—All the zinc material treated in Montana in 1935 was slag from the lead smelter at East Helena, treated in a fuming plant by the Anaconda Copper Mining Co.; the output was nearly twice that in 1934.

Lead-zinc ore.—The output of lead-zinc ore was nearly doubled in 1935. All of it was treated by flotation, and most of it came from the Orphan Girl and Emma mines at Butte, the Comet mine near Basin, and the Trout mine at Philipsburg.

Ore sold or treated in Montana in 1935, by counties, with content in terms of recovered metals

METALLURGIC INDUSTRY

Of the 2,412,113 tons of material produced in 1935 in Montana, 232,860 tons (9.65 percent) were treated at gold and silver mills, 1,924,826 tons (79.80 percent) were treated at concentration mills, 130,986 tons (5.43 percent) were shipped direct to smelters, and the rest (123,441 tons) was treated at a slag-fuming plant.

Of the total material treated at gold and silver mills, 4,757 tons were treated at straight amalgamation plants, 117,420 tons at straight cyanidation plants, and 110,683 tons at combined amalgamation or cyanidation and concentration plants. The following table summarizes operations at gold and silver mills in 1935.

The following table gives the total crude ore of smelting grade produced in Montana in 1935. In addition, 7,701 tons of old tailings, etc. (chiefly siliceous), were shipped for smelting, copper precipitates from Butte mine waters were shipped to the Anaconda smelter, and zinc slag was treated at a fuming plant.

² Includes items entered as "(1)" above.

In the following review by counties and mining districts, only the more important operations are mentioned. Many small producing mines and several districts and counties whose output is included in the foregoing tables are omitted from this review.

BEAVERHEAD COUNTY

The Ermont mine near Argenta was operated the last 6 months of 1935, and about 4,300 tons of gold ore were shipped to Anaconda for smelting; operations continued in 1936, and the company built a new 100-ton cyanidation plant, which was placed in operation in November 1936. The Shafer mine (Argenta district) was operated in 1935 by the Steele lease, and about 5,800 tons of gold ore were shipped for smelting; in 1936, the Shafer property, together with the Ground Hog and several other mines in the district, was acquired under lease by the Argenta Consolidated Goldfields, Inc., and a new cyanidation plant was under construction in 1936. The Thompson Gold Milling Co. continued operations at the Sleeping Princess mine at Bannack in 1935 and treated nearly 14,000 tons of ore by cyanidation (the company also shipped ore from the adjoining Gold Bug mine for smelting); the Sleeping Princess mine and mill were idle during 1936. The Quartz Hill Mining Co. shipped about 6,900 tons of silver ore of smelting grade from the Lone Pine & Argyle Silver and Aurora properties in the Vipond district in 1935; operations continued in 1936, and production increased to nearly 8,800 tons.

BROADWATER COUNTY

The Vosburg Mining Co. completed a new 50-ton cyanidation plant at the Vosburg group in the Beaver district, and in 1935 milled more than 14,000 tons of gold ore; operations continued in 1936, but the output of gold was only half that in 1935. The Keating property near Radersburg was acquired in 1935 by the C-G Gold Corporation. A new 100-ton flotation mill was completed and placed in operation in September 1935, and several thousand tons of dump ore were milled; milling operations on dump ore continued in 1936, and the production of gold (in flotation concentrates) was nearly three times that in 1935.

DEER LODGE COUNTY

A group of claims, including the Holdfast, Short Shift, and Oro Fino, in the Georgetown district, was acquired in 1935 by Thomas H. Sheridan, and a new cyanidation plant was under construction at the property at the end of the year; but the only production in 1935 was lessees' ore shipped for smelting. In 1936 the new mill was placed in operation, the output of gold increased markedly, and the mine became the most important producer in Deer Lodge County. The Gold Coin Mines Co. operated the Gold Coin mine and mill in 1935 and treated more than 12,000 tons of gold ore by amalgamation and concentration; commercial ore reserves were exhausted, however, and in 1936 the company was re-treating old tailings by cyanidation. Lessees continued shipping gold ore of smelting grade from the Southern Cross mine at about the same rate in both 1935 and 1936.

FERGUS COUNTY

There were no important producers in Fergus County in 1935, but in 1936 the North Moccasin Mines Syndicate was organized to acquire the old Barnes-King property 20 miles north of Lewistown. A 50-ton cyanide plant was built and placed in operation in August 1936, and several thousand tons of gold ore were milled by the end of the year.

FLATHEAD COUNTY

The Anaconda Copper Mining Co. continued shipments of silver ore from the Flathead mine near Kila in both 1935 and 1936. More than 18,000 tons of ore were shipped to the smelter at Anaconda in 1935, but the 1936 output decreased about 10 percent.

GRANITE COUNTY

The Trout Mining Co. continued regular operations at the Trout & Algonquin property at Philipsburg in 1935 and 1936 (the company abandoned its incorporated status in 1936, and operations continued as the Trout Mining Division of American Machine & Metals, Inc.). The company completed the construction of a 50-ton flotation plant at Philipsburg in 1935 and treated about 7,300 tons of partly oxidized silver-lead-zinc ore in the new mill before the end of the year (the new mill treated about 23,000 tons of ore in 1936); in addition, regular shipments of ore to the zinc-flotation plant at Anaconda continued in both 1935 and 1936. The total output of all classes of ore in 1935 was about 46,000 tons; in 1936 the output increased to about 64,000 tons. The Philipsburg Mining Co. built a new 160-ton flotation plant (replacing the mill destroyed by fire in 1934) at the Granite Bimetallic mine in 1935 and milled about 25,000 tons of silver ore before the end of the year; the output was more than doubled in 1936. The Silver Prince Mining Co. was reorganized as the Contact Mines Corporation in May 1936; regular shipments of lead-zinc ore to the mill at Anaconda were continued in both 1935 and 1936. Lessees acquired the Two Per Cent mine near Philipsburg late in 1935 and in 1936 shipped more than 9,000 tons of siliceous silver ore to Anaconda for smelting. The Lakes Mining & Milling Syndicate was reorganized as the Hidden Lake Venture, Inc., in September 1936; in 1935 the company treated about 16,000 tons of ore in the 75-ton cyanidation plant, and in 1936 the output of gold increased more than 50 percent.

JEFFERSON COUNTY

The Basin Montana Tunnel Co. continued operations at the Comet & Gray Eagle property at a normal rate in both 1935 and 1936. In 1935 nearly 59,000 tons of lead-zinc ore were treated in the 200-ton flotation mill, and in 1936 about 62,300 tons were milled. The output of gold and silver increased in 1936, and the company was by far the most important producer in Jefferson County. The Basin Gold Mines, Inc., treated more than 14,000 tons of dump ore from the Jib mine in the 300-ton flotation mill in 1935; in 1936 the mill was not operated, but about 2,800 tons of siliceous ore were shipped for smelting. The United Gold Mines Corporation acquired the Mount Washington mine (Colorado district) in 1935 and began construction of a 150-ton flotation mill; a little lead-zinc ore was shipped to the Comet mill in

1935, and in January 1936 the new mill was placed in operation and more than 14,000 tons were treated. The Winston Bros. Co. continued operations at the placer property on Prickly Pear Creek north of Clancy in both 1935 and 1936 at a normal rate (the 1936 output was slightly greater than that in 1935). The floating washer and dragline excavator were dismantled late in 1936 and moved 500 feet to a new location; operations were resumed early in 1937.

LEWIS AND CLARK COUNTY

The Golden Messenger mine in the Dry Gulch district was operated continuously in 1935 and 1936; about 36,400 tons of gold ore were treated in the 125-ton cyanidation plant in 1935, and the output increased to about 44,300 tons in 1936. The Montana Consolidated Mines Corporation resumed production at the Spring Hill mine on March 16, 1935 (after a mine strike had been settled), and operated continuously for the remainder of 1935 and all of 1936; in 1935 about 76,800 tons of ore were treated in the 300-ton flotation plant, and in 1936 more than 93,200 tons were milled. The Porter Bros. Corporation completed the erection of a 4,500-cubic-yard electric dredge at the Last Chance Gulch property near Helena in November 1935 and operated continuously from November 3, 1935, to the end of the year and all of 1936 except a short time in February. About 282,000 cubic yards of gravel were dredged in 1935, and in 1936 the dredge handled nearly 1,769,000 cubic yards; the company was the largest producer of gold in Montana in 1936. The Anaconda Copper Mining Co. operated the slag-fuming plant at East Helena on current lead-smelter slag continuously in both 1935 and 1936; the 1936 output of zinc fume was considerably less than that in 1935. At the Gould mine near Wilborn the Standard Silver-Lead Mining Co. produced 26,389 tons of ore in 1935 and 27,691 tons in 1936; the ore was treated in an 80-ton cyanidation plant.

LINCOLN COUNTY

Most of the production from Lincoln County in 1935 was gold ore from the Keystone mine (Sylvanite district) treated by amalgamation and flotation and lead-zinc ore from the Giant Sunrise property (Troy district) treated by concentration.

MADISON COUNTY

In 1935 the Liberty Montana Mines Co. treated 13,530 tons of ore from the Mammoth & Leviathan mine in the 150-ton flotation mill; the output increased to 19,662 tons in 1936. The Pacific Gold Mining Co. milled nearly 15,000 tons of ore from the Boss Tweed & Clipper mine in 1935, and the output was about the same in 1936. The Boaz mine was the most important producer in the Norris area in 1935; the mine was operated by the Jack Pot Mining Co., and nearly 2,300 ounces of gold were produced in ore of smelting grade. The Mayflower mine near Renova was reopened in July 1935 by the West Mayflower Mining Co. (Anaconda Copper Mining Co.), and about 2,200 tons of gold ore were shipped for smelting; in 1936 the company increased the output to more than 7,400 tons. The Golden Rod Mining Co. continued operations at the Golden Rod mine in the Silver Star district in 1935 and 1936, but the 1936 output was considerably less than that in 1935. The Humphreys Gold Corporation completed the erection

of a 5,000-cubic-yard dry-land dredge at its Alder Gulch property in June 1935, and from July 1 to December 31 the company handled 412,121 cubic yards of gravel in the new plant. The dredge was the most important producer in the Virginia City region in 1935, and in 1936 the company became the second largest producer of gold in Montana. Most of the lode-mine production at Virginia City in 1935 came from the Prospect and Marietta mines; there was a decrease in lode production in the district in 1936.

PARK COUNTY

In 1935 the Jardine Mining Co. treated nearly 39,000 tons of ore by amalgamation and concentration and produced more than 6,000 ounces of gold; in 1936 nearly 41,000 tons of ore were milled, but the gold output decreased sharply. The McLaren Gold Mines Co. operated the New Years Gift mine for 4 months in 1936; nearly 4,300 tons of ore were treated in the rebuilt amalgamation and concentration mill, and more than 1,200 ounces of gold were produced, a marked increase from the 1935 output.

PHILLIPS COUNTY

The Little Ben Mining Co. operated continuously at the August mine in 1935 and 1936; nearly 33,000 tons of ore were treated in the 100-ton cyanidation plant in 1935, and about 43,000 tons were milled in 1936. The Ruby Gulch Mining Co. shipped about 1,100 tons of rich gold ore to a smelter in 1935 and started construction of a cyanide plant; the new mill was completed and placed in operation in 1936 and the output of gold was nearly twice that produced in 1935.

POWELL COUNTY

The Pioneer Placer Dredging Co. continued operations at the 6,000-cubic yard electric dredge on Gold Creek, Pioneer district, at a normal rate in both 1935 and 1936; about 1,945,400 cubic yards were dredged in 1935, and in 1936 the dredge handled about 1,576,500 cubic yards of gravel. The dredge ranked first in placer production in Montana in 1935 but dropped to third place in 1936. The dredge of Yuba Consolidated Goldfields, in Ophir Gulch, which started operations in January 1934, ran until July 1935, when it was dismantled and moved to a placer in California. Most of the remainder of the placer output from Powell County in 1935 came from the Fontana placer of the El Dorado Gold Placer Mining Co. in Washington Gulch; the company operated the dragline and portable washing plant from April to November in both 1935 and 1936. Most of the lode-mine output from Powell County in 1935 was siliceous ore from the Emery mine in the Zozell or Emery district, which was operated by Tweedy Bros. Corporation, a lessee, and nearly 12,000 tons of gold and silver ore were treated in the rebuilt flotation plant; however, the lessee gave up the property in March 1936, and the 1936 production decreased sharply.

SANDERS COUNTY

The American Smelting & Refining Co. continued regular operations at the Jack Waite property in the Eagle district in both 1935 and 1936. The property extends over the State line into Shoshone

County, Idaho, and part of the 1936 output came from the Idaho side. In 1936 the output (from Montana) consisted of 37,000 tons of lead-zinc ore of milling grade and 1,084 tons of lead ore of smelting grade, a marked increase from 10,776 tons of lead-zinc ore and 377 tons of lead ore produced in 1935. The milling ore is treated in the 500-ton flotation plant at Duthie, Idaho.

SILVER BOW COUNTY

The following table gives the output from mines in Silver Bow County in 1934 and 1935; final data for 1936 are not available, but substantial increases were recorded in the output of all metals except zinc.

Production of gold, silver, copper, lead, and zinc in Silver Bow County, Mont., 1934-35, in terms of recovered metals

Year	Mines producing	Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
		<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	
1934-----	175	644, 487	3, 861. 03	2, 826, 252	62, 856, 150	10, 781, 757	42, 329, 372	\$9, 209, 595
1935-----	179	1, 611, 448	9, 039. 60	6, 547, 794	153, 928, 988	20, 604, 975	75, 292, 227	21, 935, 776

From 1882 (the first year for which detailed records are available) to the end of 1935 the mines in Silver Bow County, which includes the Butte or Summit Valley district, produced the five metals, as follows: Gold, 1,825,331.77 fine ounces; silver, 473,822,856 fine ounces; lead, 354,048,798 pounds; copper, 10,653,603,191 pounds; and zinc, 2,715,980,453 pounds. The total value of this production is \$2,210,496,035.

Butte or Summit Valley district.—In 1935, the Anaconda Copper Mining Co. produced 1,239,285 tons of copper ore of milling grade and 19,484 tons of copper ore of smelting grade (compared with 456,909 tons of mill ore and 304 tons of smelting ore in 1934); in 1936 the output of milling ore increased to 1,840,738 tons and smelting ore to 24,100 tons (in addition, in 1936 the company re-treated 545,530 tons of old copper tailings by combined acid-leaching and flotation and smelted 18,125 tons of pond slimes). These increases resulted in a gradual gain in the output of blister copper at the smelter, and the copper plant was operating at near capacity at the end of 1936. The output of lead-zinc ore from the Orphan Girl and Emma mines increased 156,106 tons compared with 1934, and the 1936 output was about the same as that in 1935; there was a decrease, however, of about 10 percent in the production of net zinc in 1936 compared with 1935.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA

Eureka County.....	449		

The output of gold, silver, copper, lead, and zinc from Nevada ores, gravel, and re-treated tailings in 1936, in terms of recovered metals, was 284,700 fine ounces of gold valued at \$9,964,500; 4,970,000 fine ounces of silver valued at \$3,849,265; 135,650,000 pounds of copper valued at \$12,479,800; 24,610,000 pounds of lead valued at \$1,132,060; and 31,570,000 pounds of zinc valued at \$1,578,500—a total of \$29,004,125. In 1935 Nevada mines yielded 188,031 ounces of gold valued at \$6,581,085; 4,393,426 ounces of silver valued at \$3,157,775; 74,266,000 pounds of copper valued at \$6,164,078; 25,352,000 pounds of lead valued at \$1,014,080; and 31,072,000 pounds of zinc valued at \$1,367,168—a total of \$18,284,186. For each metal the value of the output increased substantially. Gold increased 51 percent in both quantity and value, silver 13 percent in quantity and 22 percent in value, copper 83 percent in quantity and 102 percent in value, and zinc 2 percent in quantity and 15 percent in value; lead decreased 3 percent in quantity but increased 12 percent in value. The total calculated value of the metal output in 1936 exceeded that in 1935 by \$10,719,939 (59 percent) and was the largest in any year since 1929. The value of gold production exceeded that in any year since 1915, although the quantity produced in 1936 was exceeded as late as 1918. Of the total value of the five metals in 1936, gold contributed 35 percent, silver 13 percent, copper 43 percent, lead 4 percent, and zinc 5 percent. During 1936 White Pine County was the largest contributor to the nonferrous mineral wealth of the State, and the rising price of copper during 1936 was a favorable factor in continuing the expansion of metal production in this area. The high price for gold and silver stimulated mining in such districts as Tonopah, Manhattan, and

¹ Figures for 1936 are preliminary; detailed data with final revisions will be released later.

² The assistance of L. F. Janssen is acknowledged.

Round Mountain in Nye County and the Comstock Lode in Storey and Lyon Counties. The Pioche district again led in zinc and lead production. Lessees were very active in many of the camps in the State, and several new producing companies were added to the list of organizations already on a productive basis.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.646464 per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ Figures for 1936 not yet available.

Gold.—The mine production of recoverable gold in Nevada in 1936 was close to 284,700 fine ounces valued at \$9,964,500, an increase of 51 percent in both quantity and value over 1935. Exact figures are not available on proportionate contribution of lode and placer mines, but the data at hand indicate that almost all the gold was derived from lode properties as in 1935, when only 4 percent came from placer operations. In 1935, 74 percent of the lode gold produced in Nevada came from dry gold ore, but reviving activity at the base-metal mines, notably in the Robinson district in White Pine County, probably decreased the proportion from this type of ore in 1936. The higher price of silver was an important factor in the production of gold as the two metals so commonly accompany each other in the ores of the State. The four largest gold properties, listed approximately in order of their importance as producers, were as follows: Nevada Consolidated Copper Corporation (White Pine County), Goldfield Consolidated Mines Co. (Esmeralda County), Black Mammoth Consolidated Mining Co. (Esmeralda County), and Nevada Porphyry Gold Mines, Inc. (Nye County). In addition, there were many small producers of gold in the State.

Silver.—Recoverable silver produced in Nevada is closely calculated at 4,970,000 fine ounces valued at \$3,849,265 in 1936, compared with 4,393,426 ounces valued at \$3,157,775 in 1935. This represents an increase of 13 percent in quantity and 22 percent in value over 1935. The higher price of silver established by the United States Treasury in 1935 continued to stimulate mining in the State. Nye County was the leading producer of silver, followed in order by Lincoln, White Pine, and Storey Counties; the order was the same also in 1935 and 1934. Preliminary figures for 1936 indicate that Nye County continued as the leading silver producer by a wide margin, but reviving copper mining in White Pine County where silver is a byproduct and precious-metal mining in Esmeralda County seemed likely to have upset the order in which the other counties had stood. A few of the major silver producers derived their silver from straight argentiferous ores, but most of the silver output of Nevada came as a byproduct of gold, copper, lead, and zinc mining. The companies with the largest output of silver, listed approximately in the order of their importance, were as follows: Treadwell Yukon Co., Ltd. (Nye County), The Tonopah Mining Co. of Nevada (Nye County), Combined Metals Reduction Co. (Lincoln County), Nevada Consolidated Copper Corporation (White Pine County), General Metals Recovery Corporation (Esmeralda County), and Arizona Comstock Corporation (Storey County). The remainder of the silver output of Nevada came from a large number of small properties.

Copper.—The mine output of recoverable copper in Nevada is closely calculated as 135,650,000 pounds valued at \$12,479,800 in 1936. This increase of 83 percent in quantity and 102 percent in value over 1935 returned copper to first place, with respect to value, among the metals produced in Nevada; gold had enjoyed this distinction since 1931. The Nevada Consolidated Copper Corporation in White Pine County produced far more copper than all other mines in the State together, but a substantial and increasing output was reported in Elko County by the Mountain City Copper Co., which is affiliated with the Anaconda Copper Mining Co.

Lead.—The mine production of recoverable lead in Nevada is closely calculated at 24,610,000 pounds valued at \$1,132,060 in 1936, compared with 25,352,000 pounds valued at \$1,014,080 in 1935; this is a decrease of 3 percent in quantity but an increase of 12 percent in value. Lincoln and Nye Counties were the leading producers of lead in both 1935 and 1936. Most of the production came from two companies, the Treadwell Yukon Co., Ltd., at Tybo (Nye County) and the Combined Metals Reduction Co. at Pioche (Lincoln County). Small outputs, many of them in the form of shipping ore, were reported from a large number of mines throughout the State. The two leading producers of lead in the State mined lead-zinc ore, and at both properties the precious-metal content of the ore was a very important factor in the revenue obtained.

Zinc.—The mine production of recoverable zinc in Nevada is closely calculated as 31,570,000 pounds valued at \$1,578,500 in 1936, compared with 31,072,000 pounds valued at \$1,367,168 in 1935, an increase of 2 percent in quantity and 15 percent in value. The bulk of the zinc production, like that of lead, came from the Combined Metals Reduction Co. at Pioche (Lincoln County) and the Treadwell Yukon Co., Ltd., at Tybo (Nye County).

MINING INDUSTRY

Expansion of copper and gold production was the outstanding feature of the year 1936. Until 1936 the mining industry of the State was helped more by price-raising legislation than by free metal markets. During 1936, however, expanding consumption of copper, lead, and zinc and sharply rising prices toward the close of the year proved to be dominant factors in the return of prosperity to Nevada mineral industries. Continuation of the consumption and price levels estab-

lished during the early months of 1937 would result in the most profitable period that the mineral industry of the State has enjoyed for several years. No State in the Union depends so much on the mining industry for the livelihood of its citizens as does Nevada, and the number of properties being prospected, developed, and equipped is encouraging.

METALLURGIC INDUSTRY

Data available by May 24, 1937, do not include detailed information on the Nevada metallurgic industry for 1936. Most of the mills operating in 1935 continued to do so in 1936, and substantial additions were made to the State milling capacity during the year; new plants were built and additions or improvements made at old ones. The increased production of copper ore in the Robinson district considerably augmented the output of the only smelter in the State, the copper smelter at McGill. This plant depended chiefly on ores produced by its owner, the Nevada Consolidated Copper Corporation, but it did a substantial custom business on ores purchased largely for fluxing. Custom mills were operated in various parts of the State; important ones were at Silver City, Lyon County; Midas, Elko County; Seven Troughs, Pershing County; and Searchlight and Goodsprings, Clark County. Large quantities of ore were shipped out of the State, principally to the lead and copper smelters in the Great Salt Lake Basin. The Bauer (Utah) plant of the Combined Metals Reduction Co. treated all the company lead-zinc ore mined at Pioche. The 300-ton flotation mill completed by the Mountain City Copper Co. in the Cope district was an important addition to the metallurgic equipment of the State.

¹ Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; other producing districts listed in footnote 6 and output included under "Undistributed."

² Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

³ Of the total silver, 4,360,817 ounces came from lode mines and 2,669 ounces from placers.

⁴ No information as to number (see footnote 2).

⁵ Tonopah district lies in both Esmeralda and Nye Counties.

⁶ Includes following districts: Tybo, Nye County, and Black Horse, White Pine County.

CHURCHILL COUNTY

Fairview district.—The Nevada Mines, Inc., worked the Nevada Hills mine in 1936 and made a number of shipments of gold-silver ore in December; a 40-ton cyanide plant was under construction. The Lena and the Chalk Mountain mines were both active.

Wonder district.—Lessees worked the Nevada Wonder mine from June 1936 until the end of the year and made a number of shipments of gold-silver ore for smelting.

Other districts.—Prospecting, development, and a small output were reported from the Alpine, Aspen, Holy Cross, Jessup, and Sand Springs districts during 1936.

CLARK COUNTY

The completion of Boulder Dam was the most important event in Clark County during 1936, and the mining interests of the area expressed the hope that cheap electric power from this source would contribute to the further revival of the local mineral industries. So far, however, higher prices for the metals had been the principal factor in improving mining conditions.

Crescent district.—Several small operations were reported in the Crescent district in 1936, including work on the Budget, the Treasure, and the Colonel Sellars property. Ore was shipped both for smelting and for treatment at custom mills at Searchlight about 20 miles to the east.

Eldorado Canyon district.—The Eldorado-Rand Mining Co. treated a large quantity of tailings by cyanidation and concentration between June and October 1936; gold was the principal metal recovered. Activities were also reported at the Boulder Eldorado, Duncan, Techatticup, Silver Legion, Dolores, and Yellow Ned properties.

Searchlight district.—The Searchlight district was the outstanding producer in Clark County in 1936, and its old mines were actively developed. Most of the mills in the camp depended more or less upon custom ore, and the opportunity for lessees and sublessees usually was greater than in other Nevada districts. The Mollin Mining Co. operated a flotation mill at the Quartette mine and treated principally old tailings; some custom milling was also done. The Esler Douglas amalgamation mill treated ore for a number of shippers, most of whom were local lessees. The Kelsey Mining & Milling Co. cyanided ore and old tailings for various shippers. The Blossom mine, one of the larger producers of the district, was operated by lessees and sublessees.

Yellow Pine district.—The Chiquita mine was the largest producer in the Yellow Pine district in 1936. The company operated a 100-ton cyanide plant; the recovered content was mostly gold. The mill at the Keystone Barefoot property was operated largely on custom ore, and the mine itself was worked by lessees. The Golden Chariot was worked throughout the year, and 500 feet of development work were done. Smaller production was reported at the Boss, Red Cloud, Yellow Horse, and Clementina mines.

DOUGLAS COUNTY

Amalgamation of a small quantity of gold ore in 1936 was reported at the Mammoth mine in the Silver Glance district.

ELKO COUNTY

Contact district.—Lessees worked the Delano group in 1936.

Cope district.—The Mountain City Copper Co., subsidiary of the International Smelting Co., operated the Mountain City mine throughout 1936 and was the largest producer of high-grade copper ore in the United States. During the year a 300-ton flotation mill was built, and over 4,700 feet of development work were done. Before the mill was completed large quantities of ore averaging over 25 percent copper were shipped; the precious-metal content of the ore was negligible. The company paid dividends for the first time in 1936 and by the close of the year had distributed \$497,810.67.

Delano district.—Lessees developed the Cleveland and Hendrix claims during 1936; a small quantity of lead ore resulting from this work was shipped. Lessees on the Delno mine shipped considerable argentiferous lead ore. Favorable results were reported from development work at the Rainstorm, Larabelle, and Johnny Boy group of claims.

Gold Circle district.—The companies operating near Midas continued production and development at their properties throughout 1936. The largest operation was that of the Gold & Silver Circle Mines, Inc., on the Elko Prince and Missing Link mines; in addition, the company did considerable custom milling for other properties nearby. The gold ore mined also contained a substantial amount of silver and was treated at a countercurrent cyanidation mill. The Buena Gold Mines, Inc., worked the Esmeralda mine throughout the year and treated the ore by amalgamation and cyanidation. As at the Elko Prince and Missing Link properties, the value of the ore was in both gold and silver. The Sleeping Beauty was developed by the East Standard Mining Co., which drove 400 feet of development headings during the year; the ore taken out was stored on the dump. More than 1,000 tons of old tailings were shipped from the Kansas mine to the Gold & Silver Circle mill for treatment.

Jarbridge district.—The Elkoro Mines Operating Co. worked the Elkoro mine, the outstanding producer in the Jarbridge district in 1936. The ore was treated in a 250-ton flotation mill, and the concentrates containing gold and some silver were shipped to a smelter. This mine was shut down in 1932 as worked out, but the higher prices for gold and silver have made its reopening possible. The Alpha mine was operated intermittently during the spring and summer months; the ore produced was treated by amalgamation and the sands by cyanide leaching.

Lime Mountain district.—The Lime Mountain Consolidated worked throughout 1936 and shipped copper ore for smelting; almost 1,000 feet of drifts and raises were driven. The ore was reported to contain considerable copper and zinc in addition to the precious metals.

Mardis district.—A new tunnel 160 feet long was driven at the Virginia mine in 1936, and a small quantity of ore resulted from this development.

Railroad district.—Lessees worked the Sweepstake mine in 1936 and made a number of shipments.

Spruce Mountain district.—The Black Forest mine was worked by the Missouri Monarch Consolidated Mines Co. throughout 1936. Over 1,600 feet of development work were done, and the ore produced therefrom was shipped for smelting. Although the ore is complex it

is mined chiefly for its lead and silver content. The Nevada Lead & Zinc Co. shipped ore of similar type.

Tuscarora district.—Prospecting and development work was carried on in the Tuscarora district in 1936, and small quantities of lode and placer gold were produced.

ESMERALDA COUNTY

Desert district.—Three lessees worked in the Mammoth and Last Chance mine in 1936 and treated their output by amalgamation in a 15-ton Chilian mill; some other small operations were reported in the district.

Divide district.—Various lessees shipped considerable gold-silver ore in 1936 from the property of the Tonopah Divide Mining Co. for smelting. The property of the Brougher Divide Mining Co. was likewise worked by lessees, and the silver ore produced was shipped to a smelter. Lessees carried on development work at the Diamondfield Daisy and Texas Kelly mines, and production was reported from each.

Goldfield district.—An increase of mining activity in the Goldfield district in 1936 was brought about by exploration work (following geological recommendations) by the Eastern Exploration Co. operating as a subsidiary of the Calumet & Hecla Consolidated Copper Co. The exploration work was done on the properties of the Goldfield Consolidated, Goldfield Deep Mines Co. of Nevada, Jumbo Extension Mining Co., and East Extension Mining Co. Although the tonnage of ore produced was small, some of it had a gold content reminiscent of early-day production, and its total gross value was large. Development work exceeded 13,000 feet. An enlarged changehouse and a new compressor were added to the surface equipment. The other large producer in the Goldfield district was the Bradshaw Syndicate, Inc., which held a lease on the tailings of the Goldfield Consolidated Mines Co. Except in the winter months this company operated a 1,400-ton cyanidation plant throughout the year and treated 325,000 tons of old tailings with a large recovery of gold. The Jumbo Extension Mining Co., Reorganized Silver King Divide Mining Co., and Imperial Development Co. were among other operators in the district.

Hornsilver district.—The Ohio Mines Corporation operating the Orleans group in 1936 continued to be the principal producer in the Hornsilver district. The company treated its ore in a 75-ton flotation mill and shipped the concentrates for smelting. The value of the ore lies chiefly in gold, but silver was a substantial contributor to the revenue. A number of smaller operators were reported active in the district.

Lida district.—The Bonanza property in the Lida district was operated throughout 1936 and gold ore was shipped for smelting; 200 feet of development work were reported. A 20-ton concentrating mill was built at the Ingalls mine, where some ore was treated and concentrate produced in a test run. There was also some placer production in the district, particularly in the Tule Canyon section where the Los Angeles Rock & Gravel Corporation operated a large dry-land dredge.

Lone Mountain district.—The Weepah mine was operated by the Weepah Nevada Mining Co. and was the only producer of importance in the Lone Mountain district in 1936. The company used the open-cut method of mining and loaded the ore by power shovel into trucks

for delivery to its 250-ton amalgamation and flotation mill. Part of the gold in the ore was recovered by amalgamation, but the flotation unit accounted for the recovery of the bulk of the silver. The construction of a 300-ton cyanidation plant was reported started at the end of the year.

Silver Peak district.—The revival of mining activities in the Silver Peak district continued throughout 1936, and the Mary mine of the Black Mammoth Consolidated Mining Co. was the largest producer in Esmeralda County. The ore was treated in a 100-ton cyanidation plant; gold was the metal of principal value recovered. The Brodie mine was purchased from R. H. Gordon and the Gordon Mines, Inc., by the International Smelting Co. on April 9. The new company did 931 feet of development work and treated its ore in a 15-ton amalgamation-flotation mill. The principal value of the ore is the gold content. Humphrey & Holt operated a 50-ton cyanide-leaching plant on old tailings in the district.

Tonopah district (see also Nye County).—The General Metals Recovery Corporation, leasing the huge tailings dump at Millers from The Tonopah Mining Co. of Nevada, was one of the large producers of gold and silver in Esmeralda County during 1936. These tailings were the result of early-day treatment of Tonopah ores before water had been developed at the mines themselves; Millers was the nearest point at which abundant water was available. The mines of the Tonopah district lie several miles to the east in Nye County.

EUREKA COUNTY

Buckhorn district.—The Buckhorn Mining Co. started operation on the Buckhorn mine in April 1936. A 100-ton flotation mill was built, and milling was begun on November 1. Concentrate valued principally for gold was shipped for smelting.

Cortez district.—Ore shipments were made from the property of the Consolidated Cortez Silver Mines Co. and from the Schultes mine during 1936. The former shipped silver ore and the latter gold-silver ore.

Diamond district.—A small quantity of lead ore was shipped in 1936 from the Silver Bell property.

Eureka district.—The Eureka Prospect worked throughout 1936 on the Diamond Excelsior property and recovered a large quantity of gold and a substantial quantity of silver by cyanidation. A little gold ore was shipped. The mill ore was given a chloridizing roast before cyanidation. A number of lessees working in Eureka district made numerous shipments of argentiferous lead ore.

Lynn district.—The Big Six property was worked in 1936 by a lessee, who made a number of shipments of gold ore for smelting. Most of the operations in the Lynn district, however, were on placer ground. Placer production was reported from the Arrowhead, Big Six, Bullfrog, Gold Coin group, Golden Tip, Hilltop, Last Chance, Mayday, Payday, and Spotted Horse properties. Much of the work was done by small-scale hand methods, but a small power shovel and special concentration machine were reported on the Golden Tip property. Both wet- and dry-concentration methods were emp'

HUMBOLDT COUNTY

Awakening (Amos) district.—The Awakening district in the Slumbering Hills, a few miles south of Sodhouse, was the scene of Nevada's most spectacular gold rush of 1936. In 1935 two prospectors located some claims in this area, which were subsequently taken over by George B. Austin, of Jungo. The mine was named the Jumbo, and the grass-roots ore proved rich enough to make the mine virtually self-financing. By the end of the year the deepest work was about 150 feet below the surface, and a 25-ton mill was amalgamating the ore produced. The publicity incident to the Jumbo development resulted in a small rush to the district and in considerable prospecting and development work.

Boyd Basin district.—The Homer Verne mine was operated from April to November 1936 under lease and produced a small quantity of gold ore which was treated by amalgamation.

Gold Run district.—A number of small operations were reported in the Gold Run district during 1936.

Leonard Creek district.—Operations on the Black Rock and Treadwell properties were turned over by E. F. Nieman on November 5, 1936, to the Columbia Mines, Inc. During the year several lots of gold ore were shipped for smelting, and over 600 feet of development work, including 80 feet of sinking, were done.

National district.—The Buckskin-National mine, worked by the Nevada Lucky Tiger Mining Co., was the largest operation in the National district in 1936. A large quantity of ore and a smaller quantity of old tailings were treated at an all-slime cyanidation plant having a daily capacity of 50 tons. Development headings were driven 350 feet during the year. The National mine was worked by lessees who shipped bullion and ore during the year.

Potosi district.—The Getchel Mines, Inc., employed an average of 25 men during 1936 in developing its property on Kelly Creek in the Potosi district; 2,990 feet of development work were done.

Sawtooth district.—A number of operators were reported using dry-washing methods on the Black Joe property during 1936.

Winnemucca district.—The Humboldt mine shipped several lots of gold ore and the Pansy Lee shipped gold-silver ore in 1936 for smelting.

LANDER COUNTY

Battle Mountain district.—Several mining operations were active in the Battle Mountain district during 1936. The properties of the Copper Canyon Mining Co. were operated both on company account and by lessees who shipped a large quantity of copper ore for smelting. Over 2,500 feet of development work were done on the property, not including that done in the leased sections. The company operations were restricted to the development of the gold-bearing sections of the Canyon mine, while the lessees' work was confined to the Copper Basin properties. No stoping was done by the company. Ore shipments to a smelter were reported from the Bailey Day, Buzzard, Florence, Gold Butte, Gold Crown, Harriet, Lucky Strike, Morning Glory, and Morning Star properties. A tailings dump at the New Bonanza mine was treated by flotation.

Bullion district.—A large quantity of gold ore was treated by cyanidation in a 30-ton cyanide-leaching plant at the Gold Acres mine in

1936. Smelter shipments of gold ore were made from the Gold Pan and Gelding properties. The Gray Eagle Mining Co. shipped a small lot of gold-silver ore for smelting and did 100 feet of development work during the year. Expansion of operations was projected at this property for 1937. A number of placer operations were reported in the Bullion district; most of the gold recovery was by dry-washing methods.

Hilltop district.—Ores containing considerable quantities of gold and silver were shipped from the Blue Dick, Hilltop, and Paymaster properties in 1936.

New Pass district.—Ore produced at the Thomas W. mine was amalgamated in a 5-stamp mill in 1936.

Pittsburgh district.—Several operators were reported to have shipped ore from the Pittsburgh district in 1936.

Reese River district.—The Austin Silver Mining Co. was the largest operator in the Reese River district during 1936. This company not only treated considerable ore from both underground workings and dumps but also did some custom milling during the year.

LINCOLN COUNTY

Comet district.—Lessees operated the Prince mine throughout 1936 and shipped a considerable tonnage of lead ore for smelting. Copper ore was shipped from the Comet mine, and 128 feet of development work were done during the 3 months the mine was worked.

Eagle Valley district.—The Blue Bird group was worked by the Blue Bird Mining Co. throughout 1936. This company operated a 25-ton flotation mill during the earlier part of the year and made several shipments of concentrates. During the latter part of the year crude ore was sent to a smelter.

Ferguson district.—The Caliente Cyaniding Co. cyanided a large quantity of old tailings in 1936, which yielded gold and a little silver. A small tonnage of gold ore was shipped for smelting from underground operations at the Delamar property.

Groom district.—Smelting ore was shipped in 1936 from the Kelly and Groom properties in this area.

Highland district.—In 1936 the Highland Queen and the Whaley mines produced lead and silver ores, respectively, for shipment to a smelter.

Jack Rabbit district.—Lessees shipped ore, carrying silver, copper, and lead, from the Ida May mine in 1936.

Pioche district.—The Pioche district continued in 1936 to be one of the leading mining districts in Nevada; during the year it was the largest producer of lead and zinc in the State. The Combined Metals Reduction Co., operating a large group of claims in the district, treated its ore by selective flotation at Bauer, Utah; the concentrates containing zinc, lead, silver, and gold were shipped for smelting. The Pioche Mines Consolidated was another very large operator in the camp. Most of the ore produced was treated by flotation, although a small quantity was shipped crude. The principal value of its ore is in silver, gold, and lead. Over 1,700 feet of development work were done during the year. Several small operators were reported in the district, most of whom were leasing.

Tempiute district.—The Tempiute Mining Co., working the Sterling group, was the largest producer in the Tempiute district in 1936. This company shipped silver ore to a smelter.

LYON COUNTY

Palmyra district.—At the beginning of 1936 the Como Mines Co. and the Stone Cabin Consolidated Mines, Inc., employed large forces at mines of this district. Before the close of the year, however, both companies had stopped operations.

Pine Grove district.—The Cambridge Mining Co. reopened an old mine 24 miles southeast of Yerington and treated a small quantity of ore in 1936 by amalgamation and table concentration.

Silver City district.—The Dayton Consolidated Mines Co. was the largest operator in Lyon County in 1936 and one of the leading gold producers of the State; the ore was treated in a 125-ton cyanide plant, and large quantities of gold and a little silver were recovered. The Trimble stamp mill (amalgamation) and the Donovan cyanide plant, both of which did custom work, were features of the mining activities of the Silver City district and were important factors in making possible the operation of many of the small mines there. The South Comstock Gold Mines, Inc., worked intermittently during the year, operating its 50-ton amalgamation and flotation mill. Part of the ore was produced by lessees. The Dayton Douglas Cyanidation Co. continued to leach the Dayton tailings in its open-air cyanide plant. In addition to the output of numerous lessees who worked lode properties in the district, a small quantity of placer gold was produced.

MINERAL COUNTY

Garfield district.—The West End Consolidated Mines Corporation of Tonopah leased its Mable mine during 1936; lessees made a number of shipments of lead ore and recovered some bullion by amalgamation.

Pilot Mountain district.—Ore produced during the 6 months the open-cut at the Belleville mine was operated in 1936 was treated by amalgamation.

Pine Grove district.—The Sunny Slope property was operated the last 2 months of 1936; a small quantity of gold was recovered at its 5-stamp amalgamation mill.

Regent district.—A number of small operators worked mines in the Regent district in 1936. Several carloads of gold ore were shipped from the Morning Star mine. Gold ore was shipped from the Black Eagle property also.

Santa Fe district.—Shipping ore was produced in 1936 at the New Year claims in the Santa Fe district.

Silver Star district.—A large number of properties were operated in the Silver Star district during 1936. The Hyde group of claims was worked by leasers. The Mary Ann and Triumph group yielded ore which was treated by amalgamation. Production of shipping ore was reported at the Cleopatra mine.

NYE COUNTY

Athens district.—Lessees worked the Warrior mine during 1936.

Bellehelen district.—Lessees were active at several mines in the Bellehelen district in 1936.

Bullfrog district.—The General Milling Corporation, working the Homestake property in 1936, treated a large quantity of ore in its 100-ton amalgamation-concentration mill. A number of shipments of gold ore were made from the Polaris property. The Gibraltar Gold Mining Co. treated a little ore in a 50-ton flotation mill.

Jackson district.—The Last Chance Mining Syndicate did 350 feet of development work and extracted a small quantity of ore from the Petersen mine in 1936; part of the ore was shipped and the remainder amalgamated. The War Eagle property shipped gold ore for smelting. This company reported that its 300 feet of new development work had located a vein on the hitherto unprospected side of a fault. Development and production were also reported at the Evening Star and Raindrop group.

Johnnie district.—A number of small dry-placer operations were reported in the Johnnie district during 1936.

Mammoth district.—Ore was reported amalgamated at the Eary mine in 1936.

Manhattan district.—The Manhattan district was one of the most active in the State during 1936. The Goldfields of America, Ltd., carried on an extensive exploration campaign at the Mayflower and Union No. 9 properties, during which a considerable tonnage of ore was treated in a 50-ton amalgamation mill. The Manhattan Consolidated Mines Development Co. was active throughout the year. Lessees worked the property of the Nevada Coalition Gold Mines Co. and produced considerable ore, of which part was treated by amalgamation and the remainder shipped for smelting. The Reliance Mining Co. operated the Verden mine, treating both ore and tailings by amalgamation and flotation. The White Caps Gold Mining Co. worked the White Caps mine and treated a large quantity of old tailings and ore in a 100-ton cyanide plant. Development work amounted to 500 feet during the year. Other properties on which work was reported were the April Fool, Five Brothers, Jumping Jack, and Owl. Many lessees produced placer gold from the properties of the Cole-Kirchen Syndicate.

Phonolite district.—The Penelas Mining Co., the only large operator in the Phonolite district in 1936, treated by cyanidation the gold ore extracted from its Penelas mine. Approximately 1,000 feet of development work were done during the year.

Quartz Mountain district.—A number of shipments of lead ore were made in 1936 by a lessee on the San Rafael mine.

Round Mountain district.—The principal property in the Round Mountain district in 1936 was the group of claims owned by the Nevada Porphyry Gold Mines, Inc., which was optioned to the A. O. Smith Corporation in the middle of the year. It was reported that the option was extended into 1937. The property includes lode and placer ground. A very large flow of water was piped many miles into the district for use in gold-recovery plants.

Silver Bow district.—Ore was reported shipped in 1936 from the Silver Bow district.

Tonopah district (see also Esmeralda County).—The Tonopah district was given over almost entirely to lessees during 1936. Large quantities of silver and gold-silver ore were shipped from the Tonopah Belmont and the Tonopah Extension and from properties of the West End Consolidated Mines Corporation and the Tonopah Mining Co. of Nevada.

Tybo district.—The Tybo mine of the Treadwell Yukon Co., Ltd., was operated throughout 1936; the company 300-ton flotation mill worked steadily until the middle of December. The Tybo district is second only to the Pioche district in production of lead and zinc.

The value of silver contained in the lead and zinc concentrate shipped accounted for almost half of its gross value.

ORMSBY COUNTY

Voltaire district.—The Gold Edge and Athens mines were under development in 1936.

PERSHING COUNTY

Antelope (Scossa) district.—The Hawkeye was worked from March 1, 1936, to the end of the year, and the ore produced was treated in a small ball mill by amalgamation. A small production was reported from the Haystack mine which was reopened and renamed the Gold Star.

Buena Vista district.—An old tailings pond was treated in 1936 at a small cyanide-leaching plant on the Star Peak property.

Kennedy district.—Shipments of gold ore in 1936 were reported from the Gold Note and Black Hawk properties.

Rochester district.—The Rochester Plymouth Mines Co. operated a flotation mill in 1936 and shipped concentrates for smelting. Silver ore was shipped from the Crown Hills and Olive properties. Gold ore produced at the Great Western Mines Co. properties was amalgamated. The Rhyolite Placers operated a gas shovel and stationary washing plant in Limerick Canyon and produced considerable placer gold.

Rosebud district.—The Golden Juniper mine was operated under lease by Linticum & Causten from the middle of August 1936 until near the end of the year. The ore was crushed to 10-mesh and given a cyanide leach. Most of the operators in the Rosebud district, however, operated dry placers. Small placer operators using hand methods were more successful in this district than in any other district of the State.

Seven Troughs district.—A number of small operators, several of them lessees, produced considerable ore in the Seven Troughs district during 1936.

Sierra district.—In 1936 several mines, both lode and placer, were operated in the Sierra district; the Black Hole mine of the White Bear Mining Co. was one of the largest.

STOREY COUNTY

Comstock district.—The Arizona Comstock Corporation, working the Savage, Hale & Norcross, and Chollar-Potosi, treated a large quantity of ore at its 400-ton flotation-cyanidation plant in 1936; the cyanide plant handles 5 tons of concentrates a day. Most of the ore was derived from the company open-cut, where it was loaded with power shovels into trucks for delivery to the mill. In the Gold Hill section of the Comstock Lode the leading producers were the Consolidated Chollar Gould & Savage Mining Co. Overman mine from which a large tonnage of ore, principally from dumps, was treated in a 300-ton flotation mill, and the Sutro Tunnel Coalition, Inc., Crown Point mine from which a large tonnage of gold-silver ore was treated in its 100-ton cyanide plant. Over 1,300 feet of development work were done at the Overman mine and approximately 1,000 feet at the Crown Point during the year. The Sierra Nevada, Ltd., working the Sierra Nevada mine at the northern end of the "Lode", treated its ore in a

125-ton flotation plant; considerable gold and silver were recovered from the resulting concentrates. Lessees operated many small mines in the district.

WASHOE COUNTY

Peavine district.—The Fravel claim was operated under lease during the early months of 1936, and 60 feet of shaft sinking were done.

White Horse district.—A number of small operations in 1936 were reported in the White Horse district.

WHITE PINE COUNTY

Cherry Creek district.—Old tailings carrying a little gold and silver were shipped from the Cherry Creek district in 1936 to the McGill smelter. A long drainage tunnel was driven by the Nevada Standard Mining Co. to open up a section of the district.

Duck Creek district.—Copper ore was shipped in 1936 from the property of the Success Mining Co. which was operated by a lessee. Lead ore was shipped from the Carbonate Lead mine for smelting; 190 feet of development work were done at the property.

Osceola district.—The production in 1936 of considerable placer gold was reported from the Osceola district.

Piermont district.—Piermont Mines, Inc., ceased operations on its Piermont mine in May 1936 and a lessee took over the property on July 1. More than 1,500 feet of development work were reported, and concentrates carrying high silver content were shipped.

Robinson district.—The Nevada Consolidated Copper Corporation, an operating subsidiary of the Kennecott Copper Corporation, working the Ruth mine at Ruth and its great open pit at Copper Flat, was by far the largest industrial company in Nevada. In addition to its mining activities this company operated the McGill copper smelter, the only smelter in the State. Its flotation concentrator, also at McGill, has a full capacity of 15,000 tons daily. Not only was this company the largest producer of copper in 1936 but it also led all other mines of the State in production of gold during the year. The Lane City and the Phoenix Midnite groups of the Consolidated Coppermines Corporation were operated exclusively by lessors during the year; a large quantity of ore, valued chiefly for its gold content but containing a substantial quantity of silver, was shipped to the McGill smelter. A substantial output was also reported from the Manganese mining claims, and a smaller output from a number of smaller producers.

White Pine district.—A number of operations in 1936 were reported in the White Pine district, including the treatment of Smokey Mill tailings in a 10-ton cyanide plant.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEW MEXICO

(MINE REPORT)

By CHAS. W. HENDERSON and A. J. MARTIN

The total production of gold, silver, copper, lead, and zinc from New Mexico ores and gravels in 1936, in terms of recovered and estimated recoverable metals, was 33,037 fine ounces of gold, 1,163,255 fine ounces of silver, 6,332,000 pounds of copper, 13,252,000 pounds of lead, and 41,336,000 pounds of zinc. This output compares with a production in 1935 of 33,435 ounces of gold, 1,061,902 ounces of silver, 4,505,000 pounds of copper, 14,578,000 pounds of lead, and 44,252,000 pounds of zinc and shows increases of 101,353 ounces in silver and 1,827,000 pounds in copper and decreases of 398 ounces in gold, 1,326,000 pounds in lead, and 2,916,000 pounds in zinc. There were 136 lode mines and 169 placers producing in 1936, a decrease of 14 lode mines and 65 placers from 1935.

The total recorded production of gold, silver, copper, lead, and zinc (in terms of recovered metals) in New Mexico from 1848 to 1936, inclusive, compiled by F. C. Blocksom under direction of Chas. W. Henderson, has been 1,963,792 fine ounces of gold, 58,665,916 fine ounces of silver, 1,550,967,473 pounds of copper, 438,681,385 pounds of lead, and 928,769,394 pounds of zinc.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in

¹ The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25-28.

1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932-36

Gold.—The mine production of recoverable gold in New Mexico was 33,037 fine ounces valued at \$1,156,295 in 1936, compared with 33,435 ounces valued at \$1,170,225 in 1935. San Miguel County (Pecos mine) produced 34.93 percent of the total in 1936, Catron 24.44 percent, Sierra (chiefly from placers) 13.62 percent, and Colfax 9.32 percent.

The largest increases over 1935 were 1,261.51 ounces in Socorro County, 1,127.43 ounces in Catron, and 919.97 ounces in Sierra; the largest decreases were 3,275.66 ounces in San Miguel County and 906.43 ounces in Grant. Lead-zinc ore yielded 34.93 percent of the total gold; dry and siliceous ore 49.40 percent; copper, copper-lead, copper-lead-zinc, and lead ores 5.45 percent; and placers 10.22 percent.

Silver.—The mine production of recoverable silver in New Mexico amounted to 1,163,255 fine ounces valued at \$900,941 in 1936 compared with 1,061,902 ounces valued at \$763,242 in 1935. Grant County produced 38.21 percent of the total in 1936, chiefly from the Ground Hog and San Jose mines in the Central district, with most of the remainder from the Steeple Rock district; Catron County 31.36 percent, all from the Mogollon district; and San Miguel County 25.83 percent, all from lead-zinc ore of the Pecos mine in the Willow Creek district. Lead-zinc and copper-lead-zinc ores from Grant and San Miguel Counties yielded 50.77 percent of the total silver; dry and siliceous ore, chiefly from Catron and Grant Counties, 39.48 percent; and copper, copper-lead, and lead ores 9.73 percent. The quantity recovered from placers was negligible.

Copper.—The mine production of recoverable copper in New Mexico totaled 6,332,000 pounds valued at \$582,544 in 1936 compared with 4,505,000 pounds valued at \$373,915 in 1935. Chino Mines of the Nevada Consolidated Copper Corporation, which from 1848, and particularly from 1910, has produced the bulk of the State output of copper, was closed in October 1934 and remained idle until January 1937. During this period of idleness at Chino Mines most of the copper produced in the State was recovered in concentrates from copper-lead-zinc and lead-zinc ores of the Ground Hog and San Jose mines, Grant County, and lead-zinc ore of the Pecos mine, San Miguel County. In 1936 copper-lead-zinc and lead-zinc ores yielded 61.53 percent of the total copper, copper and copper-lead ores 35.86 percent, and other types of ore 2.61 percent.

Lead.—The mine production of recoverable lead in New Mexico was 13,252,000 pounds valued at \$609,592 in 1936 compared with 14,578,000 pounds valued at \$583,120 in 1935. The chief lead-producing districts in 1936 were the Willow Creek, San Miguel County; Central, Grant County; and Magdalena, Socorro County. Lead-zinc and copper-lead-zinc ores yielded 90.82 percent of the total lead.

Zinc.—The mine production of recoverable zinc in New Mexico amounted to 41,336,000 pounds valued at \$2,066,800 in 1936 compared with 44,252,000 pounds valued at \$1,947,088 in 1935. The zinc-producing districts in 1936, in order, were the Central in Grant County, Willow Creek in San Miguel County, Magdalena in Socorro County, and Pinos Altos in Grant County. The output from the Magdalena district was contained in zinc-lead sulphide ore shipped to the zinc-lead pigment plant at Coffeyville, Kans. Production from the other districts was 45,528 tons of zinc concentrates containing, as shipped, 1,216.60 ounces of gold, 106,700 ounces of silver, 834,809 pounds of copper, 921,194 pounds of lead, and 48,960,110 pounds of zinc; the average zinc content of the concentrates was 53.77 percent.

MINING INDUSTRY

A heavy loss to the mining industry and to the State of New Mexico in 1935-36 was the continued shut-down of Chino Mines of the Nevada Consolidated Copper Corporation (subsidiary of the Kennecott Copper Corporation), closed in October 1934. However, improved prices for copper in 1936 resulted in the resumption, in January 1937, of open-cut operations at Santa Rita and the operation of several units (with a total capacity of 8,000 tons a day) of the 15,000-ton flotation mill at Hurley. The Kennecott Copper Corporation report for the first quarter of 1937 predicts expansion to capacity production. In 1936 the combined tonnage of lead-zinc (including copper-lead-zinc in 1936) and zinc ores showed little change from 1935 but was 6 percent greater than in 1934. The combined tonnage of dry and siliceous gold, silver, and gold-silver ores in 1936 was 53 percent greater than in 1935 and 120 percent greater than in 1934.

Details of operations of important producers in 1936 are given in the following review by counties and districts.

To continue annual detailed statistics for New Mexico on mine production by classes of ore, methods of recovery of metals, and mining districts, the data for 1935 not available for inclusion in Minerals Yearbook, 1936, are supplied in this chapter.

ORE CLASSIFICATION

¹ Ore from 2 properties, classed as lead-zinc in 1935, became copper-lead-zinc ore in 1936.

METALLURGIC INDUSTRY

All markets for New Mexico ore and concentrates are outside the State. In 1936 copper ore and concentrates and dry and siliceous ores and concentrates were sold to the American Smelting & Refining Co. copper plant at El Paso, Tex.; to the Copper Queen copper smelter at Douglas, Ariz.; to the International Smelting Co. copper smelter at Miami, Ariz.; and to the Magma Copper Co. copper smelter at Superior, Ariz. Lead ore and concentrates were sold to the American Smelting & Refining Co. lead plant at El Paso, Tex. Zinc concentrates were shipped to the American Smelting & Refining Co. natural-gas retort plant at Amarillo, Tex.; to the Illinois Zinc Co. retort plant at Peru, Ill. (moved to Dumas, Tex., during the year); to the American Metal Co. producer-gas retort plant at Langeloth, Pa.; and to the American Metal Co. natural-gas retort plant at Blackwell, Okla. Zinc-lead sulphide ore was shipped to the Ozark Smelting & Mining Co. zinc-lead pigment plant at Coffeyville, Kans. Small lots of gold ore were sold to the Golden Cycle mill at Colorado Springs, Colo. Three mills in New Mexico treating straight gold and gold-silver ores used the cyanide process for the recovery of metals in 1936.

Selective flotation was used at all important concentration mills in New Mexico in both 1935 and 1936. The following table gives the names of the active flotation mills and the location, county, rated capacity, type of ore treated, and type of concentrate produced.

Flotation mills in New Mexico active in 1935 and 1936

CATRON COUNTY

Mogollon district.—The Mogollon district, which produced only dry and siliceous gold-silver ore, ranked second among New Mexico districts in output of both gold and silver in 1936. The largest producer of both metals was the Black Hawk Consolidated Mines Co., which operated the Little Fanny cyanide mill at Mogollon at the rate of approximately 100 tons daily for 365 days on ore from the Little Fanny, Champion, and Consolidated claims of the Little Fanny and Johnson groups. The Mogollon Consolidated Mines Co. treated ore from its Deadwood-Last Chance group by flotation concentration in the 150-ton mill which the company erected and placed in operation in 1935; the mill ran throughout 1936. The product was high-grade gold-silver concentrates, containing some copper, which were shipped to the El Paso smelter. At the Queen group the Cooney Mining Co. did 1,000 feet of development in the mine and operated its 50-ton cyanide plant intermittently at reduced capacity from June 15 to December 4. Development work was done at the Ann Arbor property; some ore and dump material were treated during test runs of the mill, resulting in the shipment of a few tons of high-grade gold-silver concentrates. Several small lots of high-grade gold-silver ore were shipped to the El Paso smelter from the Bearup property.

COLFAX COUNTY

Mount Baldy district (Baldy, Elizabethtown, Eagle Nest).—Aztec Mines, lessee of the Aztec Mines property of the Maxwell Land Grant Co. at the head of Ute Creek, operated the mine and flotation-concentration mill continuously in 1936. When flotation equipment was installed in October 1935 the mill had a capacity of 36 tons per 24 hours, but new equipment added in 1936 raised its capacity to 100 tons; the daily average treated for 365 days in 1936 was 42½ tons. The product was gold-silver-copper concentrates which were shipped to the El Paso smelter. At the Montezuma mine, also owned by the Maxwell Land Grant Co., a lessee treated 60 tons (wet weight) of ore in the small amalgamation mill at the mine and shipped some ore to the Golden Cycle mill at Colorado Springs, Colo. The owner of the Red Bandana mine produced amalgamation bullion from ore treated in a 20-ton Huntington mill with copper plates and shipped a few small lots of ore to the Golden Cycle mill. A 2-ton lot of ore was shipped from the Gold Dollar claim, and a small lot of bullion was produced at the Sulphide. A 50-ton stamp amalgamation-table concentration mill was erected at the French Henry property, and development work was done in the mine. Drift mining and hydraulicking at the Ute Creek placers and sluicing operations on South Ponil, Ute, and Willow Creeks yielded the remainder of the output from the district.

DONA ANA COUNTY

Organ district.—A 2-ton lot of lead-silver ore was shipped to the El Paso smelter from the Silver King claim, on which the owner sank 35 feet of shaft in 1936.

GRANT COUNTY

Burro Mountain district (Tyrone).—Early in 1936 lessees shipped three cars of dry silver ore containing a little gold, lead, and copper from the Contact group to the El Paso smelter. Other output from the Burro Mountain district in 1936 comprised small lots of gold ore from the Big Chief and Shamrock claims and a small lot of silver ore from the Bismuth.

Camp Fleming district (Silver City).—Most of the metal production from the Camp Fleming district in 1936 was recovered from gold-silver ore shipped at intervals throughout the year by a lessee of the old Old Man mine at the south end of Treasure Mountain about 5 miles northwest of Silver City. Part of the ore was shipped direct to the El Paso smelter; part was sold to Ira L. Wright, of Silver City, who reshipped it to the smelter. This mine was reopened in 1935 and a small quantity of ore was shipped in that year, but the production was included in the figures for the Central district. A few tons of ore were shipped in 1936 from the Silver King, Pay Day, and one other property in the Camp Fleming district.

Central district (Bayard, Fierro, Georgetown, Hanover, Santa Rita).—In 1936 the Black Hawk Consolidated Mines Co. continued to operate its 250-ton selective flotation mill 1 mile south of Hanover on custom zinc-lead-copper-silver sulphide ore from the Ground Hog and San Jose properties of the Asarco Mining Co. and on company ore of a similar type from the Combination mine. The mill feed averaged 4.64 ounces of silver to the ton, 2.70 percent copper (wet assay), 4.32 percent lead (wet assay), and 7.52 percent zinc. The mill was operated 360 days at a daily average of 203 tons. Part of the ore mined at the Ground Hog and San Jose properties was of direct-smelting grade and was shipped crude to the El Paso smelter. Operated as a unit, these two mines yielded the bulk of the silver, copper, and lead produced in Grant County in 1936 and were substantial producers of zinc. The Peru Mining Co. increased the output of lead-free zinc sulphide ore from its Pewabic mine at Hanover. The ore is shipped 60 miles by railroad to the company 500-ton flotation mill (mentioned also under Luna County) at Deming for treatment. Several hundred tons of ore produced during development at the Peerless group at Central were run through the Combination mill to test the ore. Smelting ore obtained from various other mines and dumps was shipped from the district. Chino Mines of the Nevada Consolidated Copper Corporation at Santa Rita and its 15,000-ton flotation mill at Hurley remained idle in 1936 but were reopened in January 1937. Preparations were being made in April 1937 to reopen the zinc mine and 300-ton flotation mill of the Empire Zinc Co. at Hanover, closed since April 1, 1931. A small quantity of placer gold, reported to have been mined 3 miles east of Silver City by individuals, was sold to a bullion buyer at El Paso, Tex., in 1936.

Chloride Flat district (Silver City).—Development work was carried on continuously for 11 months in 1936 at the Bremen "76" group of mines, and 12 cars of dry silver ore were shipped to the El Paso smelter. Two tons of silver-lead ore were shipped to the smelter by a lessee at another property in the Chloride Flat district.

Gold Hill district (see also Hidalgo County).—The owner of the Silver Dollar claim operated the mine intermittently throughout 1936 and produced most of the ore shipped from the Gold Hill district (Grant

County) during the year. Small lots of gold ore were shipped from the Gold Bullion and one other prospect.

Lone Mountain district.—Small lots of dry silver ore were shipped from the Bisby, Ben Hur, and Rocky Mountain claims in 1936. At the Bisby group Barron & Gleason did some exploration work, including the sinking of a 50-foot shaft. In May the company started construction work on a mill in Maud Canyon 3 miles east of Silver City, to be used for treating ore from the Bisby group and custom ores. The mill was not completed in 1936.

Pinos Altos district.—Nearly all the ore produced in the Pinos Altos district in 1936 was shipped crude to the El Paso smelter. Producing mines and dumps included the Baltimore, Bonanza No. 3, Campo Santo, Cleveland, Gillette-Manhattan, Golden Giant, Hazard, North and South, and Wild Bill. A car of zinc concentrates produced at the Metcalf mill at Pinos Altos during experimental milling of ore reported to have come from the Silver Hill mine was shipped to the Amarillo (Tex.) zinc smelter early in 1936. The quantity of placer gold produced by individuals engaged in panning, rocking, and sluicing near Pinos Altos was smaller in 1936 than in 1935.

Steeple Rock district.—All the ore mined in the Steeple Rock district in 1936 was dry and siliceous gold-silver ore containing a small percentage of copper and was shipped crude to copper smelters at Miami, Magma, and Douglas, Ariz., and El Paso, Tex. The largest producer of metals was the East Camp group, followed in order by the Norman King and Billali groups. These three mines yielded 83 percent of the total output of gold in the district and 86 percent of the silver. The remainder came from the Alabama (old stock pile shipped), Carlisle, Homestake, Jim Crow, and Summit mines and two prospects.

White Signal district.—A small lot of gold ore was shipped from the Combination claim in the White Signal district in 1936, and a little gold was recovered by sluicing at two small placers.

HIDALGO COUNTY

Eureka district (Hachita).—Ore produced in the Hachita district in 1936 was shipped to the El Paso smelter or was sold in small lots to ore buyers at Douglas, Ariz. A car of sorted ore from the Hard-scrabble dump yielded most of the gold; lead-silver ore from the Lead Queen, Mariposa, and Wilcox properties yielded most of the other metals. A little placer gold recovered from the Bader placer was sold to the Denver Mint early in 1936.

Gold Hill district (see also Grant County).—Small lots of smelting ore were shipped from three prospects in the Gold Hill district in 1936.

Lordsburg district (including Pyramid and Virginia or Shakespeare districts).—In 1936 the Banner Mining Co., lessee of the Bonney Mine group, did considerable development work in the mine and erected a 200-ton mill to treat the siliceous copper-gold-silver ore of the group by flotation concentration. The mill began operations in August and ran continuously the remainder of the year but not at full capacity the entire period. The product was copper-gold-silver concentrates which were sold to the El Paso smelter. Other producers in the district shipped their ore to smelters in Texas and Arizona or sold it in small lots to buyers of ore at Silver City, N. Mex., and Douglas, Ariz. Among the producing mines and prospects were the Atwood group, Battleship, and Misers Chest, all worked by lessees.

San Simon district (Steins).—The Hattie Lee (old Beck) mine was operated by lessees from January 14 to November 1 and was the only producer of more than a car of ore in the San Simon district in 1936. Silver was the metal of chief value in the ore, which was shipped crude to smelters. The other output from the district comprised silver-copper ore from the Guadalupe claim.

LINCOLN COUNTY

Jicarilla district.—Most of the output from the Jicarilla district in 1936 was small lots of placer gold produced in the Jicarilla Mountains southeast of Ancho by individuals and prospectors who sold the gold to merchants at Ancho and Carrizozo. A power shovel and special sluicing installation were operated from November 1 to December 31 at the Ancho and Rico claims and recovered nearly all the rest of the output from the district. William Little moved a power shovel and Ainalay-bowl recovery plant to the Turner-Moody group 1 mile east of Jicarilla and made tests on the ground during September and October.

Nogal district.—The Helen Rae mine was operated intermittently on a small scale in 1936. Bullion was recovered in a small amalgamation plant at the mine, and some ore was shipped to the El Paso smelter. Late in the year equipment comprising a 75-ton ball mill and amalgamation plates was installed at the Great Western property, from which a small lot of bullion was shipped to the Denver Mint. Some development work was done at the Silver Plume and Bonita groups. A little placer gold was recovered on Day Gulch south of Nogal.

White Oaks district.—Test runs, for a short period early in 1936, of the flotation mill at the property of the Lincoln County Mining & Milling Co. resulted in the shipment of a few truckloads of lead-silver concentrates to the El Paso smelter. A small lot of ore was shipped from a prospect in the White Oaks district, and some development work was done at the Crown Gold Silver group. M. F. Hutter recovered placer gold by use of a rocker on Baxter Gulch.

LUNA COUNTY

Cooks Peak district.—A small lot of lead-silver ore was shipped from the "85"-Ethel group in 1936.

Deming.—The 500-ton selective flotation mill of the Peru Mining Co. at Wemple, near Deming, was operated 299 days in 1936 at an average daily rate of 450 tons on lead-free zinc sulphide ore from the company's Pewabic mine at Hanover, Grant County.

Florida Mountains district.—Lessees at the Chavez-Reinhard property shipped a few lots of lead-silver ore in 1936.

Tres Hermanas district (Columbus).—A car of lead-silver-gold ore was shipped from Columbus to the El Paso smelter in 1936.

Victorio district.—A prospector did 10 feet of development work at the Silver Branch claim in 1936 and produced a small lot of lead-silver ore which he sold to an ore buyer at Silver City.

OTERO COUNTY

Orogrande district.—The output from Otero County in 1936 was placer gold from the Orogrande district, most of which was produced

from sluicing operations at small placers. A special placer machine was operated intermittently after July at the Little Joe and Cotton Top placers and recovered some gold.

RIO ARriba COUNTY

Headstone district.—Small sluicing operations on Eureka Gulch yielded a little placer gold in 1936.

SAN MIGUEL COUNTY

Willow Creek district (Terrero).—The Pecos mine of the American Metal Co. on Willow Creek has been the largest single producer of gold, silver, lead, and zinc in New Mexico since it was opened in 1927. Operations were continuous in 1936 except for an interruption caused by a miners' strike during part of February and all of March and April. The ore is transported over a 12-mile aerial tram from the mine to the company selective flotation mill in Alamitos Canyon 6 miles by road from Glorieta station and 4 miles by railroad spur from Fox station on the Atchison, Topeka & Santa Fe Railway. The mill treated an average of 574 tons daily for 263 days in 1936. The heads of ore into the mill in 1936 averaged 0.102 ounce of gold and 3.08 ounces of silver to the ton, 0.67 percent copper (wet assay), 3.55 percent lead (wet assay), 9.58 percent zinc, and 12.33 percent iron. The yield from 150,932 dry tons of ore treated in 1936 was 21,544 tons of zinc concentrates—averaging 0.056 ounce of gold and 3.52 ounces of silver to the ton, 1.12 percent copper (wet assay), 1.01 percent lead (wet assay), 54.06 percent zinc, and 8.11 percent iron—and 11,106 tons of lead-copper concentrates—averaging 0.99 ounce of gold and 24.51 ounces of silver to the ton, 4.35 percent copper (wet assay), 37.47 percent lead (wet assay), 10.13 percent zinc, and 12.53 percent iron.

The Cristino Rivera Mining Co., at its property in sec. 27, T. 18 N., R. 12 E., New Mexico principal meridian, sank 90 feet of shaft from May 12 to December 31, 1936, making the total depth of the shaft 180 feet.

SANTA FE COUNTY

Ortiz Mountains district (Cerrillos).—In 1936 the Ortiz Mining Co. unwatered the Ortiz mine on the Ortiz Grant southeast of Cerrillos and shipped a few cars of gold-silver-copper ore to the El Paso smelter; in March 1937 the company sold its lease to the Santa Cruz Mining Co., which started work on straightening the 250-foot shaft and repairing mine timbering at other underground workings. Small lots of gold ore were shipped early in 1936 from the Benton mine near the Ortiz, but the Benton mine was idle most of the year.

San Pedro or New Placers district.—Lessees at the La Santa Fe group in 1936 recovered small lots of bullion from high-grade gold ore found in small quartz veins. A car of gold-silver-copper ore was shipped from the San Pedro group to the El Paso smelter. Small sluicing and dry-washing operations yielded placer gold which was marketed through mercantile establishments or sent direct to the Denver Mint.

SIERRA COUNTY

Chloride (Apache, Cuchillo Negro) district.—In 1936 lessees at the Great Republic mine 15 miles by road northwest of Winston shipped several lots of siliceous gold-silver ore containing a little copper to the El Paso smelter. The 35-ton gravity- and flotation-concentration mill at the mine was run for a short period late in the year. In March 1937 the mine was leased by another company which in April was shipping 10 to 15 tons of ore a day to the El Paso smelter. The Fortuna and Ivanhoe claims each shipped a 1-ton lot of ore in 1936, and prospects in the district shipped 3 tons.

Hermosa district.—The only output from mines in the Hermosa district in 1936 was 10 tons of lead-silver ore reported to have come from the Pelican group.

Kingston district.—Lessees operated the Keystone mine in the Black Range Mountains on North Percha Creek part of 1936 and shipped several cars of dry silver ore to the El Paso smelter. The other producer in the Kingston district was the Miners Dream-Smiling Jane group which shipped small lots intermittently during the year.

Lake Valley district.—The only producing mine in the Lake Valley district in 1936 was the Lake Valley group which, although producing chiefly manganese ore, yielded one car of gold-silver-lead ore (containing a small percentage of copper) which was shipped to the El Paso smelter.

Las Animas district (Hillsboro).—In 1936, as in 1935 and 1934, the John I. Hallett Construction Co., operating the Animas Consolidated and Slease leases (a consolidation of the old Gold Dust and other placers, totaling 1,200 acres), was the largest producer of placer gold in the Hillsboro district and in the State. The equipment used in 1936 comprised two Northwest dragline excavators, each with a capacity of 1,200 cubic yards per 24 hours, and a portable Coulter-Ainlay recovery plant with four Ainlay 36-inch bowls using gasoline engines for power. Operations were continuous in 1936, and the company handled 100,000 yards of material. There were no other important individual producers from placers in the district in 1936, but scattered small-scale operations contributed to the placer output.

The largest producer from lode mines in the Hillsboro district in 1936 was the Wicks mine in Wicks Gulch, operated continuously by A. A. Luck; the ore was shipped crude to the El Paso smelter. The only other producers of as much as a car of ore were the Biglow-Empire-Bonanza and Portland-Sherman-Caballero groups.

Pittsburg district.—At the property of the Pittsburg Placer Mining Co., lying between the Rio Grande River and the Caballo Mountains 3 miles northeast of Arrey, the Consolidated Mines, Inc., operated its dragline excavator and sluicing equipment for about 2 months in the first part of 1936 and then shut down; later, operations were started by W. T. Warnick, who continued production until December. This property was the second largest producer of placer gold in the State in 1936. Small sluicing operations in the Pittsburg district yielded 43 fine ounces of gold.

SOCORRO COUNTY

Magdalena district.—In 1936 the Kelly mine group of the Empire Zinc Co. was operated continuously under lease to Kenneth Hughes until December 15, when operations were discontinued. The mine

produces zinc-lead sulphide ore. The entire output in 1936 was shipped to the Ozark Smelting & Mining Co. at Coffeyville, Kans. A car of gold ore was shipped from the Morning Star mine to the El Paso smelter, and several lots of lead-silver-gold ore were shipped from the Queen group.

Rosedale district.—In 1936 the Rosedale Gold Mines, Ltd., operated its 75-ton cyanidation mill for 324 days on ore from the Rosedale mine, at an average daily rate of 50 tons. The mine is opened by a 700-foot shaft and approximately 1 mile of drifts. The ore is crushed, ground, and classified; the overflow from the classifier goes to a Deister table, from which the heads go to the smelter and the tails to cyanide tanks. Precipitation is accomplished in zinc boxes. Gold-silver bullion recovered is sold to the mint. A new conveying system and one new crusher were added to the mill equipment in 1936.

San Mateo Mountains district.—The Springtime Mining Co., which has been developing the Panky mine and producing some ore annually since 1934, continued operations until the latter part of 1936, when the company closed the mine. The ore in both 1936 and 1935 was treated in a 40-ton flotation mill at the mine. A small quantity of gold bullion was recovered by hand in 1936 from ore found at a prospect a few miles south of the Panky mine.

TAOS COUNTY

Red River district.—The Myrtle Mines, Inc., operated the Jay Hawk claim from January 1 to April 1, 1936, and treated 500 tons of ore in the 35-ton flotation mill at the property. The product was gold-silver concentrates, which were shipped to the El Paso smelter. In October the Taos Mining & Milling Co. took over the Jay Hawk claim and the Caribel property under bond and lease. A 1-ton lot of gold ore was shipped from the Midway claim to the Golden Cycle mill at Colorado Springs, Colo.

In 1936 the Molybdenum Corporation of America continued operations at the Phyllis group on Sulphur Creek. The molybdenum ore is treated in the company 40-ton (per 24 hours) flotation mill at the junction of Sulphur Creek and Red River above Questa.

TORRANCE COUNTY

Carocito district.—A car of copper ore was shipped from Encino to the El Paso smelter in 1936.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN OREGON

(MINE REPORT)

By CHARLES WHITE MERRILL and H. M. GAYLORD

SUMMARY OUTLINE

The output of gold, silver, copper, lead, and zinc from Oregon ores, gravels, and re-treated tailings in 1936, in terms of recovered metals, was 60,753 fine ounces of gold valued at \$2,126,355; 85,061 fine ounces of silver valued at \$65,880; 574,000 pounds of copper valued at \$52,808; 158,000 pounds of lead valued at \$7,268; and 122,000 pounds of zinc valued at \$6,100—a total of \$2,258,411 for the five metals. In 1935 Oregon mines yielded 54,160.11 ounces of gold valued at \$1,895,604; 110,385 ounces of silver valued at \$79,339; 397,800 pounds of copper valued at \$33,017; and 59,575 pounds of lead valued at \$2,383—a total of \$2,010,343 for the four metals; no output of zinc was reported for 1935. Both the quantity and value of all the metals except silver increased substantially over 1935. Gold increased 12 percent in both quantity and value; copper, 44 percent in quantity and 60 percent in value; lead, 165 percent in quantity and 205 percent in value; and zinc was produced in 1936 following complete cessation of output in 1935. Silver decreased 23 percent in quantity and 17 percent in value.

The total value of the metal output was 12 percent greater in 1936 than in 1935; moreover, the upward trend in quantity production carried the total value in 1936 above that in any year since 1917. Gold has provided the principal revenue of the metal miners of Oregon and in 1936 accounted for 94 percent of the total value of the five metals.

Baker County continued to be the leading metal producer of the State, followed closely by Grant County, and these two counties accounted for over two-thirds of the total value. Most of the remainder came from Josephine, Jackson, and Lane Counties, but some metal output was reported from 11 other counties.

Placer mines yielded approximately two-thirds of the State output of gold in 1936; the leading producing counties, in order of importance, were Grant, Baker, Josephine, and Jackson. Many of the placer operators mined during only a few weeks or months, often because of scarcity of water; on the other hand, a small group of dredge and hydraulic operators worked almost continuously throughout the year.

Five conventional dredges of the connected-bucket type handled 5,148,000 cubic yards of gravel in 1936, which yielded 17,067.26 fine

ounces of gold; the average value of recovered gold per cubic yard treated was 11.6 cents.

Equipment consisting of a power shovel of the dragline type delivering gravel to a floating washing plant is designated a "dragline dredge." Four such operations handled 2,066,000 cubic yards of gravel in 1936 to recover 12,989.42 fine ounces of gold, an average recovery of 22 cents per cubic yard.

Operations using power shovels or other types of mechanical excavators to deliver gravel to nonfloating washing plants are designated "dry-land dredges." Six such operations handled 136,000 cubic yards of gravel in 1936 to recover 1,479.21 fine ounces of gold, an average recovery of 38.1 cents per cubic yard.

Fifty-two hydraulic operations reported the extraction of 2,677.05 fine ounces of gold in 1936 from 1,051,000 cubic yards of gravel, an average of 8.9 cents per cubic yard. The gravel treated at the 20 drift operations reported was very much higher in grade, averaging \$2.726 in gold per cubic yard; the total recovery of gold from drift mining was 422.21 fine ounces. The remaining 4,785.85 fine ounces of the placer-gold output were recovered by miners using small-scale hand methods, of whom 79 reported they worked mines or claims; a very much larger number apparently worked the creeks as snipers. No dry placering was reported.

The largest producers in 1936 among the dredging companies were: Ferris & Marchbank in Grant County, using a dragline dredge, and the Sumpter Valley Dredging Co. in Baker County, the Rogue River Gold Co. in Josephine County, and the Timms Gold Dredging Co. and the Monarch Gold Dredging Co. in Grant County, all four using the connected-bucket type of dredge.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932-36

Year	Gold	Silver	Copper	Lead	Zinc
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1932.....	¹ \$20.67+	\$0.282	\$0.063	\$0.030	\$0.030
1933.....	25.56	.350	.064	.037	.042
1934.....	34.95	² .646+	.080	.037	.043
1935.....	35.00	.71875	.083	.040	.044
1936.....	35.00	.7745	.092	.046	.050

¹ \$20.671835.

² \$0.64646464.

¹ The Treasury from Feb. 1, 1934, through December 1934 [has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25-28.

Mine production of gold, silver, copper, lead, and zinc in Oregon, 1932-36, in terms of recovered metals

Year	Mines producing		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1932.....	99	169	5, 195	19, 861. 21	\$410, 568	8, 616	\$2, 430
1933.....	111	292	11, 557	20, 239. 66	517, 326	20, 760	7, 266

Gold.—The production of gold in Oregon in 1936 was 60,753 fine ounces valued at \$2,126,355, an increase of 12 percent in both quantity and value over 1935; 65 percent of the total came from placer mines and 35 percent from lode properties. Production from lode properties declined slightly more than 100 ounces, but that from placers increased almost 7,000 ounces. Baker County yielded over half of the lode-gold output of the State and over one-fourth of the placer gold; Grant County, whose total gold output was somewhat less than that of Baker County, led in output of placer gold. Almost all the rest of the gold produced in the State in 1936 came from Josephine, Jackson, and Lane Counties. Virtually all the gold, other than that recovered from gravel, was derived from dry gold ore or from old siliceous tailings. More than half of the lode gold was recovered by concentration followed by smelting of the resulting concentrates. Among placer operators a large increase was recorded in production by connected-bucket dredges and dragline dredges, but there was a sharp decline in output by hydraulic and small-scale hand methods. Drought affected hydraulic and most of the hand methods adversely, and returning prosperity undoubtedly tended to reduce greatly the number of snipers on the creeks.

Silver.—The production of silver in Oregon in 1936 amounted to 85,061 fine ounces valued at \$65,880, a decrease of 23 percent in quantity and 17 percent in value from 1935. Baker County yielded over half and Grant County almost one-fourth of the State total. Nearly 90 percent of the silver produced came from dry gold ores. Concentration followed by smelting of the resulting concentrates was the principal method of recovery.

Copper.—The output of copper in Oregon was 574,000 pounds valued at \$52,808 in 1936 compared with 397,800 pounds valued at \$33,017 in 1935. All the copper produced in 1936 came from Baker, Douglas, and Lane Counties, where most of it was recovered as a byproduct of the concentration of dry gold ores; copper ore was produced in Douglas County.

Lead.—The production of lead in Oregon in 1936 amounted to 158,000 pounds valued at \$7,268, an increase of 165 percent in quantity and 205 percent in value over 1935. Nearly 90 percent of it was reported from Lane County.

Zinc.—The output of zinc in Oregon in 1936 totaled 122,000 pounds valued at \$6,100 and was reported as recovered from ore mined in Lane County; no output was recorded for 1935.

MINE PRODUCTION BY COUNTIES

MINING INDUSTRY

The increased price of gold during the last few years has been particularly favorable to the Oregon metal-mining industry, because most of the metal output of the State (94 percent of the value in 1936) is accounted for by gold. A few dredges and a few lode mines, operated almost exclusively for gold, accounted for the larger part of the State metal production. The dragline dredge has been the outstanding factor in Oregon's increasing gold production in the last few years. The reopening of old lode mines, however, has also contributed substantially to the output. So far, the expansion in the metal-mining industry has centered about gold.

Gold produced at placer mines in Oregon, 1935-36, by classes of mines and by methods of recovery

METALLURGIC INDUSTRY

Of the 136,338 tons of ore (including 37,187 tons of old tailings) sold or treated during 1936 in Oregon, 88,494 tons were produced in Baker County; most of the remainder came from mines in Jackson and Grant Counties. Over 100,000 tons were treated in concentration mills,¹ most of which used flotation; over 30,000 tons were treated in gold and silver mills, some using amalgamation and others cyanidation, both with and without concentration; and the rest (about 2,000 tons) was shipped crude to smelters.

¹ Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; other producing districts listed in footnotes 10 and 15 and their output included under "Combined districts."

² Excludes flintner prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

³ Source of 1936 and 1937 as follows: 1935, 106,410 ounces from lode mines and 3,975 ounces from placer; 1936, 79,411 ounces from lode mines and 5,860 ounces from placers.

⁴ Orono district lies in both Baker and Grant Counties.

⁵ Grumbach district lies in both Baker and Grant Counties.

⁶ No information as to district of origin.

⁷ Johnson Creek district lies in both Coos and Curry Counties.

⁸ Grumbach district lies in both Jackson and Josephine Counties.

⁹ Mormon Basin district lies in both Baker and Malheur Counties.

¹⁰ Includes following districts: Mormon Basin, Sparks, and Sumpter in Baker County; Cape Blanco and Gold Beach in Curry County; Shively in Douglas County; and Ashland in Jackson County.

¹¹ No information as to district or county of origin.

¹² Included under "Combined districts."

¹³ Exclusive of lode output, which is included under "Combined districts."

¹⁴ Includes following placers: Baker, Bull Run, Cable Cove, Cornucopia (lode), Cow Creek, Cracker Creek, Greenhorn, Rock Creek, Snake River, Sumpter (lode), and Weatherly (placer) in Baker County; Agnes in Coos County; Chetco (lode), China Meadows, Fort Orlord, and Stars in Curry County; Cow Creek, Drew Creek, Green Valley, and Myrtle Creek (lode) in Douglas County; Goodson, North Fork John Day, Quinn, and Shively (lode) in Grant County; Haggard, Haggard, and Haggard (lode) in Harney County; Ashland, Elk Creek, Grumbach (lode), and Grumbach (lode) in Jackson County; Bohemia (placer) in Lane County; Lower Applegate (lode) and Waldo (lode) in Josephine County; Boardman in Morrow County; Camp Carson in Union County; and Spanish Gulch in Wheeler County.

EASTERN OREGON

Baker County.—In the Baker district the largest producer in 1936 was the Balm Creek Gold Mining Co., which operated the Balm Creek mine formerly worked by the Oregon Copper Co. Most of the ore from this mine was treated in the company 100-ton flotation mill, but a small quantity was shipped crude with the flotation concentrates to a copper smelter. The principal content was gold, but copper contributed substantially to the mine revenue. Over 5,000 feet of development work were done during the year, and stoping was begun on the lower levels after the mine had been unwatered. Small-scale miners operating in the district produced more than 200 fine ounces of gold.

In the Bull Run district virtually all the gold produced in 1936 came from the property operated by the Record Gold Mining Co. The company ore was amalgamated and floated, and the concentrates were shipped to a smelter; 100 feet of sinking were done at the property during the year. In addition to the lode output of the district a little gold was reported from small-scale placer mines.

In the Connor Creek district a number of small placer operators were reported at work during 1936.

In the Cornucopia district the Cornucopia Gold Mines had a larger output in 1936 than any lode mine in Oregon. Of the material treated at the two flotation mills (300-ton and 100-ton) of the company, a little over one-third was ore and the remainder old tailings; the resulting concentrates were shipped to a copper smelter. Most of the value was gold, but silver contributed substantially to the mine revenue and copper brought a smaller return. Development work during the year was reported as 15,000 feet, including completion of the 6,000-foot Coulter tunnel giving access to the deeper ore bodies. The mine and mill employed an average of 125 men throughout the year. Almost all the other output of the district came from placer operations, the largest of which was Ingram Placers, Inc., on Pine Creek, a drift mine working a glacial channel.

In the Cow Creek district in 1936 the Harrison Gold Dredging Co. worked creek gravel with a power shovel and washing plant.

In the Cracker Creek district gold ore was shipped in 1936 from the Golconda and the Argonaut properties.

In that part of the Greenhorn district extending into Baker from Grant County several producers in 1936 were reported.

In the Mormon Basin district placer mining was active in 1936. The leading producer was the Pioneer Gold Dredging Co. which worked the Clarks Creek placer; this company operated an electric dredge of the connected-bucket type, having a capacity of 4,000 cubic yards per 24 hours. A small output was reported from the Dry Horseshoe drift mine. The Rye Valley placer on Dixie Creek was worked by hydraulicking. The aggregate output of small producers in the district was substantial.

In the Rock Creek district the Highland and the Baisley-Elkhorn properties were the leading producers in 1936. At the former ore was treated by flotation, and at the latter crude gold ore was shipped for smelting.

In the Sparta district the Gem of Sparta mine was the leading producer in 1936; it was operated part of the year by the Sparta Gold Mining Co. and later by the Gem Cooperative, a group of seven men.

Development work was reported at the Macy mine and at the Gold Ridge claims.

In the Sumpter district the Mountain View property was the most productive lode-gold mine in 1936. The importance of the district, however, is due to its placer output. The leading producer was the Sumpter Valley Dredging Co., which operated an electric dredge of the connected-bucket type, having a capacity of 8,000 cubic yards per 24 hours. An average of 23 men was employed at the property throughout the year. The material worked was described as lake-bed gravel. A dry-land dredge at the Harris placer produced placer gold. In addition, a large number of small placer operators reported output.

In the Virtue district White Swan Gold, Inc., working the White Swan mine, was the outstanding producer in 1936. The company mined gold ore and treated it by amalgamation.

In the Weatherby district a number of operators made small outputs of gold in 1936 from both lode and placer mines, and considerable development work was done.

Grant County.—In the Canyon district the principal output in 1936 was placer gold. Ferris & Marchbank, the leading producer, operated a dragline dredge. The plant capacity was 6,000 cubic yards per 24 hours; the dragline used Diesel-electric power and the washing plant, Diesel power. An average of 24 men was employed at the property throughout the year. The Monarch Gold Dredging Co., another large operator, used a floating dredge of the connected-bucket type, having a daily capacity of 3,000 cubic yards; an average of 13 men was employed most of the year. Other operations in the district included both lode and placer mines.

In the Granite district gold was the principal metal produced in 1936; it came from both lode and placer properties. The most productive mine, the Hope placer on Bull Run Creek, was worked by a gasoline-powered dry-land dredge with dragline excavator and a washing plant mounted on skids. An average of 5 men was employed during the 5 months that work was carried on.

In the Greenhorn district the Ben Harrison mine, worked by the Campbell Mining Co., was the leading producer in 1936. The company built a 100-ton flotation mill which began operating May 1; during the construction period the old mine was reopened. Material treated during the year was approximately three-fourths ore and one-fourth old tailings; revenue recovered came largely from gold, but silver was a very important byproduct. About 800 feet of development work were done during the year. The Red Bird mine started operations late in 1936 and produced a small quantity of gold ore which was amalgamated. Several other small lode and placer operations were reported in the district; one of the more important was the Vinegar Creek placer, where 8,000 cubic yards of bench gravel were hydraulicked.

On the North Fork of John Day River a gasoline shovel and dry-land washing plant were used in 1936 on 6,000 cubic yards of auriferous gravel.

In the Quartzburg district a number of small lode- and placer-gold mines were worked in 1936.

In the Susanville district in 1936 the Timms Gold Dredging Co. operated an electric dredge of the connected-bucket type, having a capacity of 2,000 cubic yards per day; an average of 17 men was employed after operations were begun in March.

Other counties.—Virtually all the rest of the output from eastern Oregon in 1936 came from mines in Harney and Malheur Counties, but very small outputs were reported from Morrow, Umatilla, Union, and Wheeler Counties.

WESTERN OREGON

Coos and Curry Counties.—Placer gold was reported produced in 1936 in the Agness and Johnson Creek districts in Coos County and the Chetco, Gold Beach, Mule Creek, Port Orford, and Sixes districts in Curry County; the output from neither county was large. The largest producer was the property at Cape Blanco in Curry County, operated by Dorothy Faris and associates who worked beach sand by sluicing and produced important quantities of platinum and osmiridium along with the gold.

Douglas County.—In the Riddle district in 1936 the Silver Peak mine started operations in July and made a number of shipments of copper ore containing gold and silver; at the Huckleberry group mine operations resulted in free-milling ore which was amalgamated for gold; and several other lode mines reported smaller output, as well as prospecting and development work. Placer mining in Douglas County was most active in the Coffee Creek, Cow Creek, Drew Creek, Green Mountain, and Myrtle Creek districts; much of the output came from small operators who sold their products through local gold buyers.

Jackson County.—In the Ashland district the Ashland mine was among the 10 leading lode mines of the State in 1936 in tonnage produced and in gross value of recovery therefrom. The principal value was gold. The mine was operated throughout the year and the mill during the last 9 months. An average of eight men was employed, and mine development comprised 250 feet of new work and 2,000 feet of shaft and level reclamation following unwatering of the lower levels.

In the Elk Creek district the chief operations in 1936 were at the Al Sarena mine and the Rhyolite mining claim; at both properties the principal product was gold.

In the Gold Hill district several mines produced gold during 1936. The largest lode operation was at the Sylvanite mine, but the bulk of the district output came from placers. The Charles W. Kitts placer property was worked during the early weeks of 1936 by Rogue River Dredgers, Inc.; the equipment, a dragline dredge, lay idle some months until work was resumed under different management in August. Several other small operations were reported, and more than 600 fine ounces of gold were sold, by small-scale miners working the creeks, to gold buyers serving the district.

In the Jacksonville district the Opp mine, the largest lode operation in western Oregon in 1936, was worked by the Pacific States Mines, Inc. The company had an average of 24 men working from the first of the year until operations ceased at the end of August. The ore was treated by flotation; the resulting concentrate, the principal value in which was gold, was shipped to a smelter. The leading placer mine in the district was the Alaska of Oregon worked by the Alaska of Oregon Mines Co., which had a stationary washing plant with a capacity of 1,200 cubic yards per day; the gravel was delivered to the plant by trucks loaded by a steam shovel. Production was reported to have been incidental to testing work. There were a number of other small operations, both lode and placer, in the district, and small-scale miners selling through local gold buyers produced 300 ounces of fine gold.

In the Upper Applegate district a number of small lode and placer operations were productive in 1936. One of the largest was that at the Mountain Home drift mine, where an average of five men was employed during the first 6 months of the year. More than 200 fine ounces of gold were sold by small-scale miners in the district through local gold buyers.

Josephine County.—In the Althouse district, although there were several operators in 1936, most of the gold was recovered by hydraulicking at the Independence mine.

In the Galice district the largest operation in 1936 was that of the H. & M. Development Co., Inc., at the Oriole mine. Some old tailings were cyanided at the Bunker Hill mine, and production of gold ore was reported at the J. C. L. mine. The largest placer output in the district came from hydraulicking at the Old Channel mine, where three giants under 375 feet of head worked during the early months of the year. The Dean & Dean property also was worked by the hydraulic method. Placer operations throughout the district, however, were curtailed by the drought, which caused a serious shortage of water for mining purposes. Over 300 fine ounces of gold produced in the district passed through the hands of local gold buyers.

In the Grants Pass district a number of small operations in 1936 were reported. The total output of gold by small-scale miners selling through gold buyers exceeded 400 fine ounces.

In the Greenback district the largest lode-mine operation in 1936 was that of the Finley-McNeil Co. at the Greenback mine; the company employed an average of 10 men during the latter half of the year. Gold ore was treated in a 10-stamp mill, and 270 feet of development work were done. The largest mining operation in the district and one of the largest in the State was that of the Rogue River Gold Co., which operated an electric dredge of the connected-bucket type, having a capacity of 5,000 cubic yards per 24 hours; the company employed an average of 20 men at the dredge, exclusive of labor contracted to clear the land for mining. Carlson & Sandburg operated a dragline dredge on Coyote Creek for a short time toward the close of the year but later moved their equipment to California. Hydraulicking at the Blue Channel, Columbia, Forsythe, and H. K. Miller properties accounted for much of the remaining placer output of the district, and more than 150 fine ounces of gold produced by small-scale miners were sold through local gold buyers.

In the Illinois River district a number of small lode and placer operations accounted for the output in 1936; almost 300 fine ounces of gold were produced by very small operators, who sold their product through gold buyers.

In the Lower Applegate district the largest lode producer in 1936 was the Humdinger group; gold ore was mined and was treated in the 5-stamp amalgamation mill. The largest placer producers of the district were the Horsehead and the Oscar Creek mines. Over 100 fine ounces of gold were credited to small operators selling through local gold buyers.

In the Waldo district the Rainbow mine was the leading lode-gold producer in 1936. At the Esterly mine, formerly known as the Llano de Oro, gravels were hydraulicked. A stationary washing plant, to which gravel was delivered by power shovel and trucks, was worked at the Leonard mine during the spring months. At the

property of the Waldo Placer Mining Co. gold was recovered by hydraulicking from January to April. Almost 150 fine ounces of gold produced in the district by very small operators were sold through local gold buyers.

Lane County.—The only mining of importance in Lane County during 1936 was in the Bohemia district; the ore produced in the county was complex and contained gold, silver, copper, lead, and zinc. The Musick mine operated by the Minerals Exploration Co. was the leading mine in the district and one of the large mines of the State; most of the ore produced was treated by amalgamation and flotation, and both copper-lead and copper-lead-zinc concentrates were shipped for smelting. Smaller outputs were reported from the Evening Star and the Noonday mines. Construction and development work were carried on throughout the year at the property of the Bohemia Gold Mines, Inc.

Other counties.—The rest of the output from western Oregon in 1936 came from Lincoln and Linn Counties.

GOLD, SILVER, COPPER, AND LEAD IN SOUTH DAKOTA

(MINE REPORT)

By CHAS. W. HENDERSON and A. J. MARTIN

SUMMARY OUTLINE

	Page		
Summary.....	499	Review by counties.....	501
Calculation of value of metal production.....	499	Custer County.....	501
Mining and metallurgic industry.....	501	Lawrence County.....	502
Metallurgic recovery.....	501	Homestake mine.....	502
		Other mines.....	503
		Pennington County.....	504

Metal mines in South Dakota produced 586,353.40 fine ounces of gold and 144,448 fine ounces of silver in 1936 compared with 567,230.20 ounces of gold, 151,047 ounces of silver, and 7,000 pounds of recoverable lead in 1935. The production of gold in 1936 was the highest in any year on record and was exceeded in continental United States only by that of California; however, the producing area in South Dakota is much less than in California, comprising only parts of the three southwestern counties—Custer, Lawrence, and Pennington—in what is known as the Black Hills. As usual, the bulk of the output came from the famous Homestake mine, at Lead, Lawrence County, the largest producer of gold in the United States. Increased production by the Portland-Two Johns-Ajax group at Trojan and the Maitland group in the Maitland district, both also in Lawrence County, contributed substantially to the gain in the State total yield of gold. There were nine other producing lode mines in South Dakota in 1936. Placer operations yielded 346.80 fine ounces of gold in 1936 compared with 936.86 ounces in 1935.

The total production of gold, silver, copper, and lead (in terms of recovered metals) in South Dakota from the beginning of production in 1875 to the end of 1936, as compiled by Chas. W. Henderson, has been 17,055,717 fine ounces of gold, 8,530,474 fine ounces of silver, 195,691 pounds of copper, and 575,313 pounds of lead.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in *Minerals Yearbook*, 1934, pp. 25-28.

MINING AND METALLURGIC INDUSTRY

All the ores mined in South Dakota in 1936 were dry gold ores, comprising 1,383,929 tons treated by amalgamation followed by cyanidation of sands and slimes, 155,652 tons by cyanidation only or by roasting followed by cyanidation, 9,521 tons by amalgamation only, and 44 tons (yielding 104.69 ounces of gold and 21 ounces of silver) shipped crude to smelters. Operating details at both lode and placer mines are given in the following review by counties.

METALLURGIC RECOVERY

Gold and silver bullion produced at mills in South Dakota by amalgamation, 1932-36

Dr. C. Palmer operated equipment comprising a dragline, portable trommel screen, and sluices from July 15 to November 30, 1936, at the Kidwell property on French Creek one-half mile west of Custer;

3,000 cubic yards of overburden were removed and 1,500 yards of gravel treated. John Ross operated a three-quarter-yard dragline excavator, portable revolving screen, and sluice box intermittently from May 15 to July 5 at the Dickey placer 5 miles northwest of Custer; between 6,000 and 8,000 cubic yards of gravel were treated. These two operators produced most of the output of gold from Custer County in 1936; the remainder was recovered on French Creek by individuals with sluices, rockers, and pans. Fewer persons tried to earn a living by small-scale placer mining in the county in 1936 than in any year since 1930.

No production was made from lode mines in Custer County in 1936.

LAWRENCE COUNTY

Mine production of gold, silver, and lead in Lawrence County, S. Dak., 1932-36, in terms of recovered metals

Year	Mines producing		Ore	Gold (lode and placer)		Silver (lode and placer)	Lead	Total value
	Lode	Placer						
			<i>Short tons</i>	<i>Fine ounces</i>		<i>Fine ounces</i>	<i>Pounds</i>	
1932-----	3	17	1,409,211	479,300.90	\$9,908,029	126,103	7,000	\$9,943,800
1933-----	3	21	1,432,285	511,289.36	13,068,556	125,340	-----	13,112,425

1935-----	6	30	1,486,274	566,194.66	19,816,813	150,940	7,000	19,925,581
1936-----	5	11	1,539,409	585,379.74	20,488,291	144,253	-----	20,600,015

Homestake mine.—The Homestake mine and mills were operated continuously in 1936. The new 5,000-foot, three-compartment, 13-by 19-foot Ross shaft, begun in December 1932 and first placed in service to the 2,750-foot level (2,900 feet below the skip dump) in November 1934, had been completed and steel-timbered to 30 feet below the 3,800-foot level by the end of 1936 and was operated to the 3,800-foot level. Other development work done in the mine during 1936 comprised 24,594 feet of drifts, 11,759 feet of raises, and 10,215 feet of diamond drilling. Part of the ore produced during the year was hoisted through the Ellison shaft, where the primary crushing plant is underground; ore handled through the Ross shaft was crushed in the new crushing plant on the surface at the shaft.

For treatment the ore is moved by a rail tramway from the hoists to the South mill, which has a capacity of 3,900 tons per 24 hours. Here the ore is further reduced by stamps and fed to rod mills in closed circuit with Clark-Todd amalgamators for primary grinding and to ball mills and pebble mills in closed circuit with Clark-Todd amalgamators for secondary grinding. The copper amalgamation plates, for many years an integral part of the mill equipment, have been gradually replaced by the Clark-Todd amalgamators, but a few were still in use in 1936. Classification is done partly in the South mill but is finished in cyanide sand plant No. 1 and cyanide sand plant No. 3. In plant No. 3 part of the tailings from the South mill are classified and further ground in ball mills in closed circuit with Clark-Todd amalgamators. The sands are treated by cyanide leaching, and the slimes are thickened and sent to the slime plant at Deadwood for further treatment. In plant No. 1 a partly classified sand portion of the tailings from the South mill is separated by cone classification

into sand and slime fractions. In this plant the sands are leached, and the solutions from both this plant and the No. 3 plant are precipitated. Slimes are piped to the slime plant at Deadwood, which accomplishes cyanidation of the slimes from both plants. Precipitation is by the Merrill-Crowe process. Silver is parted from the gold in the company refinery, and virtually pure metals are shipped to the mint.

Ore from the Homestake mine to the company mills totaled 1,383,929 tons in 1936, an increase of 4,766 tons over 1935, and revenue from the sale of gold-silver bullion and a small quantity of assay laboratory slag was \$19,506,534.78—\$315,521.59 more than in 1935. Dividends paid in 1936 were \$9,041,760. From 1876 to 1936, inclusive, this mine yielded bullion and concentrates that brought a cash return of \$321,508,038 after freight, express, insurance, mint, and smelter charges were deducted; the company has paid \$97,062,202 in dividends.

The annual report of the general manager of the Homestake Mining Co. for the year ended December 31, 1936, says:

Operations in all departments during 1936 were normal. Production from the mine was slightly larger than in the preceding year and gross income for gold and silver produced set a new record.

The mine, treatment plants, and other surface plants are in excellent condition. It is expected that production for 1937 will be approximately the same as in 1936.

There are 311,921 tons of broken ore remaining in shrinkage stopes.

The reserve of developed ore is 15,270,968 tons.

The Ross shaft is completed and steel installed to 30 feet below the 3,800-foot level. The large cage was operated to that level on the last day of the year.

The No. 2 winze was completed to the 4,100-foot level with a 34-foot sump. Main drifts on the 4,100-foot level were driven 2,161 feet.

The Ross compressor plant, to replace that at the B & M shaft and to provide added capacity, is nearly completed. It will be in operation in February 1937.

Precipitation during 1936 was the lowest on record. As a result, power from the hydroplants was very low. But operations were not hampered because of ample capacity at the Kirk power station.

In the passing of Mr. B. C. Yates, general manager since 1918, everyone in the organization lost a good friend and wise leader. His loss is keenly felt.

Ore milled, receipts, and dividends, Homestake mine, 1932-36¹

Year	Ore milled	Receipts for bullion product		Dividends
		Total	Per ton	
	<i>Short tons</i>

1936.....	1,383,929	19,506,534.78	14.0950	9,041,760

¹ From 1876 to 1936, inclusive, this mine yielded bullion and concentrates which brought \$321,508,038 and paid \$97,062,202 in dividends.

Other mines.—At Trojan the Bald Mountain Mining Co. operated its all-sliming cyanide plant at an average daily rate of 306 tons for 365 days in 1936 on ore extracted from its Portland-Two Johns-Ajax-Alaska-Dakota group and some custom ore. The ore is loaded into 1½-ton cars in the mine and raised by rail tramway through an incline to the surface; the cars then travel by gravity downgrade to the mill 4,200 feet from the mine. The company did 1,875 feet of development work in the mine during the year and completed the installation of three additional thickeners and a vacuum pump to raise the capacity of the mill from 250 to 325 tons per 24 hours.

In the Maitland district the Canyon Corporation operated the Maitland mine and 110-ton roasting and cyanidation mill continuously in 1936. The mill treated an average of 102 tons daily for 365 days. The ores are refractory sulphide ores, commonly known as blue ores—gold in a siliceous dolomite gangue with pyrite and some undetermined arsenic mineral. The mine is opened by a vertical shaft with stations at the 220- and 320-foot levels. Development work done in 1936 totaled 2,348 feet. Additions to the mill in 1936 included a 30-foot Dorr thickener, 22-foot agitator, and Dorrco pump.

At the Clover Leaf property in the Bear Butte district, the Anaconda Mining & Milling Co. completed the unwatering of the seventh level and operated a section of the old 60-stamp mill intermittently after May 1936. The ore was amalgamated on plates, and the tailings were stored for treatment in a proposed new cyanide unit, on which construction was begun before the end of the year.

In the Two Bit district, the Monarch mine, which had been a continuous small-scale producer since 1932, was closed in September 1936 because the operator ran out of ore. The mine is equipped with a 25-ton cyanide mill.

Placers in Lawrence County yielded 69.40 fine ounces of gold in 1936, part of which was recovered during a short working period by an operator on Whitewood Gulch using a dragline and sluices. Small individual operators reported a shortage of water for panning and sluicing.

Activities reported at nonproducing properties in Lawrence County in 1936 were development work and repairs at the Gilt Edge, Minnesota, and Golden Crest and sampling at the Golden Reward.

Considerable diamond drilling was done by the Black Hills Mining Corporation, optionee of a property about 4 miles southeast of Deadwood.

PENNINGTON COUNTY

Mine production of gold and silver in Pennington County, S. Dak., 1932-36, in terms of recovered metals

Year	Mines producing		Ore	Gold (lode and placer)		Silver (lode and placer)	Total value
	Lode	Placer					
			<i>Short tons</i>	<i>Fine ounces</i>		<i>Fine ounces</i>	
1932-----	5	120	682	338.87	\$7,005	42	\$7,017
1933-----	1	142	270	220.78	5,643	20	5,650
1934-----	4	171	91	366.98	12,826	27	12,843
1935-----	7	135	841	566.69	19,834	72	19,886
1936-----	7	110	9,737	833.37	29,168	186	29,312

In 1936 the King of the West Mining Co. completed a 50-ton all-slime cyanide semicountercurrent decantation plant at its King of the West mine on the head of Smith Gulch about 4½ miles southwest of Rochford. The mine is opened by a vertical shaft 160 feet deep, with levels at 75 and 150 feet, and by 947 feet of drifts and 375 feet of raises; in addition, 3,440 feet of diamond drilling have been done on the property. The ore is siliceous, carrying gold and a little silver associated with pyrite and arsenopyrite. The mine was operated all of 1936; the mill was started July 22 and after completion of test runs treated a daily average of 38 tons for the remainder of the year. In

November a concentrating jig and an amalgam barrel were added to the mill equipment. Bullion recovered was shipped to the Denver Mint.

The Empire Gold Mines, Inc., did 800 feet of drifting and cross-cutting in 1936 at the Golden Slipper mine in the Hill City district and installed additional mill equipment consisting of a Denver "Sub-A" 6-cell unit, Denver mineral jig, Akins classifier, Wilfley table, and amalgamation barrel; a crusher and ball mill had previously been installed. Operations during the year were confined mostly to development work and remodeling of the mill, but several lots of amalgamation bullion recovered during testing of the equipment were shipped to the mint and some high-grade ore was sold to smelters. The Bothwell mine near Rochford was operated under lease in 1936 by the Driskill Mining Co. from January 1 to July 6 and by L. F. Thorne from July 7 to September 5. The ore was treated in a 10-stamp amalgamation mill using steam for power. Gold-silver bullion recovered was shipped to the Denver Mint. A 25-ton mill equipped with 10 stamps, amalgamation plates, and table was installed at the Marigold property in 1936, and test runs were made on ore taken from an open-cut. At the Western Bell claim, equipped with a 4-ton stamp mill, the two owners continued intermittent small-scale operations. Small lots of amalgamation bullion were recovered at the Shellerud property and Doctor No. 2 claim, and one lot of gold ore was shipped from the Nancy Lee to the Golden Cycle mill at Colorado Springs, Colo.

At the Union Hill group 3½ miles northwest of Hill City, the Ceko Mining Co. began construction of a 75-ton flotation mill in October 1936. Other properties under development in Pennington County included the Bismarck group, Joe Dollar, Holy Terror, and Three Jay—all in the Keystone district.

Sluicing operations in 1936, chiefly on Castle, Slate, Rapid, and Spring Creeks, produced small lots of placer gold, most of which was sold to bullion buyers or traded for groceries at stores in the vicinity.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN TEXAS

(MINE REPORT)

By CHAS. W. HENDERSON and A. J. MARTIN

SUMMARY OUTLINE

	Page		Page
Summary.....	507	Mines review by counties.....	509
Calculation of value of metal production.....	507	Culberson and Hudspeth Counties.....	509
Mine production.....	508	Presidio County.....	510
Smelting and refining plants in Texas.....	508		

Mines in Texas produced, in terms of recovered metals, 613 fine ounces of gold, 1,361,459 fine ounces of silver, 53,000 pounds of copper, and 935,000 pounds of lead in 1936 compared with 518 ounces of gold, 1,000,960 ounces of silver, 28,000 pounds of copper, and 1,043,000 pounds of lead in 1935. In 1936 the Presidio silver mine of the American Metal Co. in Presidio County produced the bulk of the State gold, silver, and lead; most of the copper was contained in silver ore shipped from the Plata Verde mine in Hudspeth County, a substantial producer of silver during the year. There were three other producing mines and prospects in Culberson and Hudspeth Counties in 1936, but their aggregate output was not large.

The total production of gold, silver, copper, lead, and zinc in Texas (in terms of recovered metals) from the beginning of production in 1885 to the end of 1936, according to Henderson,¹ has been 6,098 fine ounces of gold, 25,990,966 fine ounces of silver, 1,419,960 pounds of copper, 6,478,126 pounds of lead, and 1,488,474 pounds of zinc.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price²; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ For production from 1885 to 1927 and prices used in calculating values see Mineral Resources, 1927, pt. I, pp. 477-478. See also Mineral Resources, 1914, pt. 1, p. 236.

² The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in Minerals Yearbook, 1934, pp. 25-28.

Prices of gold, silver, copper, lead, and zinc, 1932-36

SMELTING AND REFINING PLANTS IN TEXAS

Custom smelters of the American Smelting & Refining Co. in Texas furnished a market for ores and concentrates from eight western States in 1936. The copper and lead plants at El Paso treated gold, silver, copper, and lead ores and concentrates from Arizona, New Mexico, and Texas and lead ore in bond from Mexico. At the end of 1936 the copper works consisted of two reverberatories, with a total annual capacity of 600,000 tons of ore, and three converters; the lead plant was equipped with three furnaces having a total annual capacity of 200,000 tons. Both plants were operated intermittently in 1936, but increasing prices for base metals late in the year permitted continuous operation of both plants to be resumed early in 1937. The reopening in January 1937 of the Chino copper mine (idle since October 1934) at Santa Rita, N. Mex., and its large concentration mill at Hurley, N. Mex., was the most potent factor affecting the operations at the copper plant, where Chino copper concentrates are treated on toll. Natural gas for fuel was introduced in these plants

in 1930.³ In 1936 the American Smelting & Refining Co. natural-gas-retort zinc-smelting plant at Amarillo treated zinc ores and concentrates from Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, and Utah. Data on the number of retorts in service in 1936 are not available, but figures published in *Minerals Yearbook*, 1935, page 113, show that the plant was equipped with 6,400 regular horizontal retorts in 1934.

In October 1936 a new natural-gas, horizontal-retort zinc smelter was completed and placed in operation 5 miles northeast of Dumas, Moore County, by the Illinois Zinc Co., which transferred its smelting activities from Peru, Ill., to take advantage of the low-cost natural gas available in Texas. During the period of operation in 1936 the company treated lead-free zinc concentrates from the Peru mill at Deming, N. Mex., operated by its subsidiary, the Peru Mining Co.

The Nichols electrolytic copper refinery at El Paso treats copper anodes produced at the Arizona smelters of the Phelps Dodge Corporation. The plant is operated by the Nichols Copper Co., which since 1934 has been a unit of the Phelps Dodge Corporation. The rated yearly capacity is 100,000 tons of anodes,⁴ but the plant was not operated at full capacity all of 1936; however, it was being run at capacity in April 1937. Natural gas has been used for fuel since the beginning of operations the latter part of January 1930.

MINES REVIEW BY COUNTIES

Culberson and Hudspeth Counties.—The Plata Verde mine in Hudspeth County, in the Van Horn Mountains 14 miles by road southwest of Van Horn, yielded most of the ore shipped from Culberson and Hudspeth Counties (output combined) in 1936. The ore is a siliceous silver ore (chiefly chlorides) containing a little copper (malachite) and occurs in a shear zone in sandstone 30 feet wide, striking north and south and dipping 48° to 50° to the west. Several thousand tons of ore were shipped to the El Paso smelter in 1936 from an open stope 100 feet long and embracing the full 30-foot width of the zone. Other development work done at the mine in 1936 and to April 14, 1937, comprised deepening to 165 feet an existing 130-foot shaft north of the stope, crosscutting 58 feet, and raising 35 feet. South of the open stope is an old timbered incline extending 246 feet westward following the dip of the zone.

From the Hazel mine in Culberson County, in the south end of the Sierra Diablo Range 16 miles northwest of Van Horn, lessees shipped several cars of silver-copper ore obtained during intermittent gouging and clean-up operations. Development work was done at the Pecos mine in the same district, and surface work and surveying were done at the Black Shaft a few miles southwest of the Hazel but in the Allamoore district in Hudspeth County. The old Caruthers mine in Hudspeth County, near the highway 6 miles west of Sierra Blanca, was operated intermittently in 1936 and yielded between 50 and 100 tons of lead-gold-silver smelting ore; the other output from the Sierra Blanca district was one lot of silver-lead ore shipped from a prospect to the El Paso smelter.

Corwin, F. R., and Harloff, C. S., *El Paso Refinery of the Nichols Copper Co.*: Min. and Met., October 1930, pp. 459-465.

Presidio County.—The American Metal Co. of Texas operated its mill at Shafter for 365 days in 1936 at a daily average of 270 tons on ore from its Presidio mine. The mine is opened by two vertical shafts, one 400 feet and one 700 feet deep, and six levels and stopes aggregating about 50 miles of underground workings. In all, 7,406 feet of drifts, raises, and crosscuts were driven and 21,300 feet of diamond drilling done in 1936. The ore is found as a replacement of limestone beds and is oxidized, the principal mineral being silver chloride, associated with argentite, cerargyrite, galena, anglesite, and cerussite. The ore hoisted through the west shaft is transported by rail tramway to the east shaft, where it is transferred to a 1-mile aerial tramway which conveys the ore from both shafts to the mill. The ore is then crushed to one-quarter inch and is ground to minus 65-mesh in a ball mill. The product is tabled for lead recovery and cyanided for gold and silver recovery. The lead concentrates and silver precipitates are shipped to the Carteret (N. J.) smelter. Electric power for the mill is obtained from a 1,200-horsepower Diesel plant.

Production of silver from the Presidio mine,¹ 1885-1936²

Tintic district.....	529		

The output of gold, silver, copper, lead, and zinc from Utah ores and gravels in 1936, in terms of recovered metals, was 223,440.00 fine ounces of gold, 9,997,645 fine ounces of silver, 252,434,000 pounds of copper, 139,772,000 pounds of lead, and 72,384,000 pounds of zinc. This output compares with a production in 1935 of 184,759.80 ounces of gold, 9,206,329 ounces of silver, 129,515,217 pounds of copper, 127,019,175 pounds of lead, and 62,213,614 pounds of zinc. There were 171 lode mines and 28 placers operating in 1936 compared with 203 lode mines and 31 placers in 1935.

Since 1864 the output of the five metals in Utah has been as follows: Gold, 7,545,095 fine ounces; silver, 624,421,861 fine ounces; copper, 5,323,628,251 pounds; lead, 7,579,535,840 pounds; and zinc, 1,175,268,050 pounds. The total value of this output has been \$1,918,311,009.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in *Minerals Yearbook*, 1934, pp. 25-28.

Prices of gold, silver, copper, lead, and zinc, 1932-36

Gold.—The output of recoverable gold in Utah was 223,444.00 fine ounces in 1936 compared with 184,759.80 ounces in 1935 and 136,581.52 ounces in 1934. The average annual output for the decade 1927-36 has been 184,325.46 fine ounces. Most of the increase in gold in 1936 over 1935 came from the Bingham or West Mountain district, chiefly from copper ore. Copper ore yielded 52.49 percent of the total gold in 1936, siliceous ore 35.96 percent, lead-zinc ore 8.83 percent, and lead ore 2.64 percent. Most of the gold from copper ore came from the Utah Copper Co. mine at Bingham which was, as usual, the largest producer of gold in Utah. Of the total gold output in 1936 concentrates of all classes yielded 61.53 percent, crude ore of smelting grade 30.41 percent, and bullion from ore to gold and silver mills 7.99 percent; placer mines yielded only 161.40 ounces.

Silver.—The output of recoverable silver in Utah was 9,997,645 fine ounces in 1936 compared with 9,206,329 ounces in 1935 and 7,111,417 ounces in 1934. The average annual output for the decade 1927-36 has been 11,363,927 fine ounces. The output of silver from each of the three principal mining areas in Utah (Bingham, Park City, and Tintic) increased in 1936. Most of the increase in silver in 1936 came from lead-zinc ore, the source of 46.91 percent of the total. Of the total silver siliceous ore yielded 30.91 percent, lead ore 11.56 percent, and copper ore 10.62 percent. Concentrates yielded 57.50 percent of the silver in 1936 and crude ore smelted 42.44 percent.

Copper.—The output of recoverable copper in Utah was 252,434,000 pounds in 1936 compared with 129,515,217 pounds in 1935 and 86,024,925 pounds in 1934. The output of copper in 1936 was the largest since 1929, when 318,282,523 pounds were produced; it was considerably larger than the average annual output (180,673,515 pounds) for the decade 1927-36. Almost all of the increase in copper in both 1935 and 1936 came from the Utah Copper mine at Bingham; the open-pit mine and mills (both Magna and Arthur) were operating at capacity during the last quarter of 1936. Copper ore (including copper from mine-water precipitates) yielded 95.89 percent of the total copper in 1936; most of the remainder came from siliceous ore and lead-zinc ore.

Lead.—The output of recoverable lead in Utah was 139,772,000 pounds in 1936 compared with 127,019,175 pounds in 1935 and 116,153,945 pounds in 1934. The output in 1936 was considerably less than the average annual output (190,844,237 pounds) for the decade 1927-36. The output of lead decreased nearly 7,700,000 pounds in the Bingham district in 1936 but increased in the Park City region, the Tintic district, and the Ophir-Rush Valley section in Tooele County. Lead-zinc ore yielded 75.28 percent of the lead in 1936, lead ore 20.15 percent, and siliceous ore 4.55 percent. Concentrates yielded 75.28 percent of the total lead, and crude ore smelted yielded the remainder.

Zinc.—The output of recoverable zinc in Utah was 72,384,000 pounds in 1936 compared with 62,213,614 pounds in 1935 and 56,396,279 pounds in 1934. The average annual output for the decade 1927-36 has been 76,944,926 pounds. Most of the increase in zinc in 1936 came from the Park City region and was due to increased production from the properties of Park Utah Consolidated Mines Co. All the zinc produced in Utah in 1936 came from zinc concentrates produced at flotation mills treating lead-zinc ore.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Utah, 1935-36, by counties, in terms of recovered metals

MINING INDUSTRY

The total value of the mine output of the five metals in Utah was \$48,836,356 in 1936 compared with \$31,651,571 in 1935 and \$22,975,534 in 1934. The value of the 1936 output was larger than that in any year since 1929 and slightly larger than the average annual value (\$46,068,160) for the decade 1927-36. The value of the copper output in 1936 increased \$12,474,165 over 1935 and accounted for nearly 73 percent of the total increase in value for the State. The increase in copper output was due entirely to increased output of copper ore from Bingham by the Utah Copper Co. The substantial gains in the output of both lead and zinc in Utah in 1936 undoubtedly would have been considerably greater if the important producers of lead-zinc ore at both Park City and Bingham had not been closed by a metal-mine strike for more than 2 months during the last quarter of 1936.

ORE CLASSIFICATION

Ore sold or treated in Utah, 1935-36, with content in terms of recovered metals

Source	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc

Gold ore.—The output of gold ore in Utah was 350,484 tons (including 83,400 tons of old tailings) in 1936 compared with 413,063 tons (including 185,293 tons of old tailings) in 1935. All the old tailings in both 1935 and 1936 were from the Manning dumps and were re-treated by cyanidation. Most (175,936 tons) of the gold ore in 1936 was smelted. Gold and silver mills treated 90,968 tons of ore and 83,400 tons of old tailings. Eleven properties in Tooele County (chiefly in the Mercur district) produced 158,133 tons of gold ore and old tailings in 1936, and six properties in Salt Lake County (chiefly in the Bingham district) produced 101,760 tons of gold ore; most of the remainder came from the Tintic district.

Gold and silver ore.—Fourteen properties produced 122,675 tons of gold and silver ore in 1936 compared with 23 mines producing 151,295 tons in 1935. All the gold and silver ore produced in 1936 was shipped crude to smelters; more than half of it came from the Bingham district and nearly all the remainder came from the Tintic district.

Silver ore.—The output of siliceous silver ore was 99,662 tons in 1936 compared with 70,813 tons in 1935. About 67 percent of the total in 1936 came from 20 properties in the Tintic district, and most of the remainder came from the Park City region.

Copper ore.—The output of copper ore in Utah was 13,774,589 tons in 1936 compared with 6,530,569 tons in 1935 and 4,092,303 tons in 1934. All but 689 tons of the 1936 output came from the Utah Copper mine at Bingham. Metals recovered from copper ore were valued at \$27,197,475, or 55.69 percent of the State total.

Lead ore.—The output of lead ore was 88,080 tons in 1936 compared with 78,332 tons in 1935. The entire production in 1936 was shipped crude to smelters; nearly half of it came from Tooele County, chiefly from the Bluestone and Honerine mines at Bauer, and most of the remainder came from Utah and Salt Lake Counties.

Lead-zinc ore.—The output of lead-zinc ore was 562,402 tons in 1936 compared with 527,513 tons in 1935. The increase in lead-zinc ore in 1936 undoubtedly would have been much greater if the chief producers had not been closed for more than 2 months due to a labor strike. More than half the lead-zinc ore produced in 1936 came from the Bingham district, and most of the remainder came from Park City. Metals recovered from lead-zinc ore in 1936 were valued at \$13,096,849, or 26.82 percent of the State total. All the lead-zinc ore produced in 1936 was treated at flotation concentrators at Midvale, Bauer, Tooele, and Park City.

Ore sold or treated in Utah, 1935-36, by counties, with content in terms of recovered metals

METALLURGIC INDUSTRY

The 14,997,892 tons of ore (including 83,400 tons of old tailings) produced in 1936 in Utah comprised 174,368 tons (including all the old tailings) treated at gold and silver mills, 14,336,482 tons (95.59 percent) treated at concentration plants, and 487,042 tons shipped crude for smelting.

Of the seven gold and silver mills active in Utah in 1936, two used straight amalgamation, one amalgamation, cyanidation, and concentration, one cyanidation and concentration, and three straight cyanidation. The following table gives data covering operations at gold and silver mills in 1935 and 1936:

Mine production of metals from gold and silver mills in Utah, 1935-36, by counties, in terms of recovered metals

County	Ore treated (dry weight)	Recovered in bullion				Concentrates and recovered metal				
		Amalgamation		Cyanidation		Concentrates produced	Gold	Silver	Copper	Lead
		Gold	Silver	Gold	Silver

¹ Included under "Undistributed."

² La Sal district lies in both Grand and San Juan Counties.

³ Detroit district lies in both Juab and Millard Counties.

⁴ Tintic district lies in both Juab and Utah Counties.

⁵ West Mountain district lies in both Salt Lake and Tooele Counties.

⁶ Includes items entered as "(1)" above.

BEAVER COUNTY

Most of the output from Beaver County in 1935 was lead-zinc ore from the Lincoln mine and siliceous ore and lead ore from the Horn Silver mine. The Lincoln mine was inactive in 1936, but shipments from the Horn Silver mine continued; most of the remainder of the 1936 output was lead ore of smelting grade from the Frisco Silver-Lead property.

BOX ELDER COUNTY

Lessees continued operations at the Vipont mine in the Ashbrook district in 1935 and 1936 and made regular shipments of siliceous silver ore of smelting grade. Most of the remainder of the Box Elder County output in both 1935 and 1936 was gold ore from the Raft River and Susannah mines in the Park Valley district.

IRON COUNTY

The entire output from Iron County in 1936 was siliceous ore from the Stateline district northwest of Modena; it comprised gold ore from the Gold Coin mine treated by cyanidation, gold ore from the Jenny and Independence mines treated by flotation, and siliceous ore of smelting grade from the Cougar, Creole, Jenny, Johnny, Ophir, Gold Hill, Independence, Burro, Blue Rock, Jumbo, and Mona properties.

In 1935 the county output consisted of silver ore from the Royal mine in the Escalante district, treated by flotation, and siliceous ore from several properties in the Stateline district, including the Gold Coin, Creole, Johnny, Ophir, Utah Spur, Exchange, and Badger mines.

JUAB COUNTY

Detroit district.—Siliceous gold ore of smelting grade containing considerable copper was shipped in both 1935 and 1936 from the Ibex mine northwest of Delta.

Fish Springs district.—Small lots of rich lead ore were shipped in both 1935 and 1936 from several properties, including the Emma, Utah, and Wilson mines.

Tintic district.—As indicated in the table that follows there were substantial increases in 1936 over 1935 in the output of gold, silver, lead, and zinc from mines in the Tintic district, including both Juab and Utah Counties; there was a slight decrease in the output of copper. Most of the increase was from mines in Utah County. The mines in both sections of the Tintic district are reviewed here.

Mine production of gold, silver, copper, lead, and zinc in Tintic district, Juab and Utah Counties, Utah, 1935-36, and total, 1869-1936, in terms of recovered metals

¹ A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

Producing mines in the Juab County section of the Tintic district in 1936 included the Centennial-Beck, Chief Consolidated, Dragon, Eagle & Blue Bell, Empire Star, Godiva, Iron Blossom, Mammoth, Plutus, Showers, Swansea, Silver Park, Gunderson, Victoria, and Yankee Girl; all of these properties except the Iron Blossom were also productive in 1935. Operations at the Mammoth mine were continuous in both 1935 and 1936; nearly 28,000 tons of ore were shipped for smelting in 1936 compared with about 23,000 tons in 1935, but the output of gold decreased about 1,500 ounces. Lessees continued shipments of siliceous ore and lead ore in 1935 and 1936 from various properties of the United States Smelting, Refining & Mining Co. at Tintic, including the Centennial-Beck, Eagle & Blue Bell, and Victoria groups; all the ore shipped was of smelting grade, and about 37,000 tons were produced each year. The Chief Consolidated Mining Co. continued operations at the Chief No. 1, Plutus, Eureka Hill, and Gemini properties in 1935 and 1936; the output in both years was chiefly lead ore and siliceous silver ore of smelting grade (a little lead-zinc ore was shipped from the Chief mine), and the output in 1936 was considerably less than that in 1935. Substantial increases in

output in 1936 over 1935 were reported at the Godiva, Empire Star, and Dragon mines.

In the eastern section of the Tintic district (Utah County) the Apex Standard, Eureka Lilly, Eureka Standard, May Day, North Lily, Tintic Bullion, Tintic Standard, Utah, Yankee, and Zuma mines were productive in 1936; all these properties were operated in 1935 except the Tintic Bullion. Large increases in output in 1936 compared with 1935 were reported at nearly all the foregoing mines and especially at the Eureka Standard and Tintic Standard properties. The Tintic Standard Mining Co. continued operations at the Tintic Standard mine in 1935 and 1936; the output of both siliceous ore and lead ore was considerably larger than in 1935. Considerably less ore was shipped from the Eureka Standard mine in 1936 than in 1935, but considerably more gold and silver were recovered. The Apex Standard mine was operated by the Chief Consolidated Mining Co., and the output increased from a few cars in 1935 to more than 6,300 tons in 1936. Production from the Eureka Lilly mine in 1936 was less than half that shipped in 1935.

MILLARD COUNTY

In 1936 gold ore of smelting grade was shipped from the E. P. H. and Charm mines in the Detroit district; in 1935 the Marette, Lone Eagle, Charm, Sunshine, and Deflation mines in the district were productive.

PIUTE COUNTY

The Annie Laurie mine in the Gold Mountain district was the most important producer in Piute County in both 1935 and 1936; siliceous gold ore was treated by amalgamation, cyanidation, and flotation, and the output of gold was considerably greater in 1936 than in 1935. The property was acquired during 1936 by the Allied Annie Laurie Gold Mines, Inc. The remainder of the county production in 1936 was siliceous ore of smelting grade from the General Connor, Deer Trail, Gold Strike, Wedge, and Arrastra properties.

SALT LAKE COUNTY

Big and Little Cottonwood districts.—The following table gives the combined output of mines in the Big and Little Cottonwood districts in 1935 and 1936.

Mine production of gold, silver, copper, lead, and zinc in Big Cottonwood and Little Cottonwood districts, Utah, 1935-36, and total, 1867-1936, in terms of recovered metals

Year	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc	Total value
		<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	
1935.....	10	1,979	160.20	38,969	40,723	542,775	100,091	\$63,111
1936.....	12	2,890	286.80	50,532	45,598	713,848	29,480	87,681
Total, 1867-1936.....	615,698	28,401.16	16,603,241	15,975,634	234,453,048	1,453,694	33,606,550

Most of the output from the Big Cottonwood district in 1935 and 1936 came from the property of the Cardiff Mining & Milling Co. In 1935 the company shipped lead ore and copper ore to smelters near Salt Lake City and lead-zinc ore to a smelter in the East; in 1936 the output was lead ore of smelting grade and lead-zinc ore sent to Midvale for milling. The remainder of the district output in 1936 was ore of smelting grade, chiefly from the Maxfield, Prince of Wales, Peruvian, Tar Baby, and Howell mines.

All the material shipped from mines in the Little Cottonwood district in 1936 was crude ore of smelting grade and came chiefly from the Alta Champion, Columbus, Columbus Rexall, and Dipper properties; these mines were also operated in 1935.

Bingham or West Mountain district.—The following tables give mine production of the West Mountain district in 1935 and 1936.

Mine production of gold, silver, copper, lead, and zinc in Bingham or West Mountain district, Salt Lake County, Utah, 1935-36, and total, 1865-1936, in terms of recovered metals

¹ A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

The Utah Copper Co. mined and milled 6,529,800 tons of ore in 1935 compared with 4,086,000 tons in 1934; the output in 1936 was 13,773,900 tons. The Arthur mill was reopened in September 1936, and during the last quarter of the year both the Arthur and Magna mills were operating at normal capacity. In addition to copper in

copper concentrates the company also recovered considerable copper in precipitates at the mine-water plant at Copperton. The company was by far the most important producer in Utah in both 1935 and 1936, and nearly all of the increase in copper production in the State came from the large open-cut mine at Bingham. The American Smelting & Refining Co. continued operations at the Boston Consolidated (Sulphide unit) of the Utah Copper Co. and in 1935 shipped nearly 48,000 tons of ore for smelting; in 1936 the output increased to nearly 71,000 tons.

The United States Smelting, Refining & Mining Co. continued regular operations at the United States & Lark and Niagara properties in 1935 and 1936. Considerably less ore was produced in 1936 than in 1935 due to the closing of the mines by a strike in October and November 1936. During 1936 the company secured the New England group of the Bingham Metals Co. by a long-term lease. The company also completed an addition to the flotation mill at Midvale, increasing the capacity to about 1,500 tons of lead-zinc ore a day.

Lessees continued operations at the Utah-Apex and Utah Delaware properties in 1935 and 1936 at a normal rate. Early in 1937 the two companies approved a consolidation agreement, and the National Tunnel & Mines Co. was formed to acquire the properties; the new company started driving a long tunnel from the Tooele side in 1937.

The output from the Park Bingham group of the Combined Metals Reduction Co. in 1935 was nearly doubled in 1936; most of the output was siliceous ore of smelting grade, but considerable lead-zinc ore is shipped to Bauer for milling.

The remainder of the district output in 1936 comprised copper precipitates shipped by the Ohio Copper Co., siliceous gold ore of smelting grade from the Utah Metal & Tunnel property, lead-zinc ore and silver ore from the Montana-Bingham group, and a little silver ore from the Opulent claim.

SUMMIT AND WASATCH COUNTIES

PARK CITY REGION

Mine production of gold, silver, copper, lead, and zinc in Park City region, Summit and Wasatch Counties, Utah, 1935-36, and total, 1870-1936, in terms of recovered metals

¹ A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

The Silver King Coalition Mines Co. continued operations at its property near Park City at about the same rate in 1935 and 1936. In 1935 the output was 101,725 tons of lead-zinc ore and 89 tons of lead ore; in 1936 it was 101,860 tons of lead-zinc ore and 353 tons of lead ore. Lead-zinc ore was treated in the company-owned flotation mill, and lead ore was shipped for smelting. The mine was closed for more than 2 months during the last quarter of 1936 due to a metal-mine strike in the district.

The Park City Development Co. continued shipments of lead-zinc ore and siliceous silver ore from the American Flag property in 1936, and production was also reported from the Daly, Flagstaff, Ontario, and City Unit (Park Utah Consolidated Mines Co.) properties.

Nearly all the output from the Wasatch County section of the Park City region in 1936 was lead-zinc ore of milling grade. The Park Utah Consolidated Mines Co. and the Park City Consolidated Mines Co. were the chief producers; most of the increase in output from the region in 1936 was due to greater output from the Judge mine of the former company. Production was also reported for 1936 from the New Park and New Quincy properties. The output of gold from the region decreased in 1936, largely as a result of the closing of the Liberty property of Park City Utah Mines Co. due to litigation.

TOOELE COUNTY

Camp Floyd (Mercur) district.—The Lewiston Peak Mining Co. and the Manning Gold Mining Co. continued regular operations at the Con Mercur mine and Manning dumps in 1935 and 1936; the companies were consolidated in 1936 into a new company called Snyder Mines, Inc. In 1935 the Manning cyanidation plant treated 185,293 tons of tailings from the old Manning dumps; in 1936 the remaining tailings (83,400 tons) in the dumps were treated. The mill also received considerable ore (nearly 17,000 tons in 1935 and more than 46,000 tons in 1936) from the Con Mercur property operated by the Lewiston Peak Mining Co. and the Snyder Mines, Inc. The output of gold from both the Con Mercur and Manning properties was considerably less in 1936 than in 1935.

The Geyser Marion Gold Mining Co. completed a new cyanidation plant at Mercur during 1935 and milled nearly 9,000 tons of ore; in 1936 the company treated nearly 25,000 tons of low-grade gold ore from the open-pit operations at the Geyser Marion mine.

Other producers in the district in 1936 included the Herschel, West Dip, and Overland (Sunshine) mines.

Ophir and Rush Valley districts.—The Hidden Treasure Mining & Development Co. shipped nearly 22,000 tons of lead-zinc ore to the mill at Midvale in 1936 compared with about 13,000 tons in 1935 and 4,000 tons in 1934; the company was by far the most important producer in the Ophir district in 1936. Nearly 3,600 tons of lead-zinc ore, silver ore, and lead ore were shipped from the Ophir Hill Consolidated property in 1936 compared with nearly 4,800 tons in 1935.

The Bluestone Lime & Quartzite Mining Co. shipped more than 28,000 tons of smelting-grade lead ore from the Cyclone & Tip Top property (Rush Valley district) in 1936 compared with about 24,000 tons in 1935. The Combined Metals Reduction Co. shipped nearly 32,000 tons of ore from the Honerine and West Calumet mines in 1936 compared with about 15,000 tons in 1935; most of the 1936 output was lead-zinc ore from the West Calumet mine treated in the Bauer mill and lead ore from the Honerine mine shipped to Tooele for smelting.

Other producers in 1936 included the Buffalo, Fisk, Kearsarge, Tintic Ophir, Queen of the Hills, Wandering Jew, Commodore, and Muirbrook properties.

UTAH COUNTY

American Fork district.—The following table gives the production from mines in the American Fork district in 1935 and 1936.

Mine production of gold, silver, copper, lead, and zinc in American Fork district, Utah, 1935-36, and total, 1870-1936, in terms of recovered metals

Year	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc	Total value
		<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	
1935.....	8	3,059	776.40	17,273	58,337	179,900	296,841	\$64,688
1936.....	7	1,680	400.40	18,652	32,272	183,500	143,480	47,044
Total, 1870-1936.....		145,692	43,641.08	2,212,109	2,285,068	32,874,443	775,828	5,322,600

Producing mines in the American Fork district in 1936 included the Blue Rock, Dutchman, Globe, Yankee, Miller, and Bog Iron properties.

Tintic district.—The mines in the Utah County section of the Tintic district are reviewed under Juab County.

The output of gold, silver, copper, lead, and zinc from Washington ores and gravels in 1936, in terms of recovered metals, was 12,217.40 fine ounces of gold, 66,900 fine ounces of silver, 204,000 pounds of copper, 1,680,000 pounds of lead, and 8,806,000 pounds of zinc. This output compares with a production in 1935 of 9,739.60 ounces of gold, 52,338 ounces of silver, 86,699 pounds of copper, 206,150 pounds of lead, and 2,159 pounds of zinc.

Since 1860 Washington has yielded an output of the five metals as follows: Gold, 1,514,508 fine ounces; silver, 9,506,380 fine ounces; copper, 27,373,495 pounds; lead, 71,971,177 pounds; and zinc, 49,517,110 pounds. The total value has amounted to \$50,715,061.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

Prices of gold, silver, copper, lead, and zinc, 1932–36

Gold and silver produced at placer mines in Washington, 1932-36, in fine ounces, in terms of recovered metals

Year	Gold	Silver	Year	Gold	Silver
1932.....	386.95	75	1935.....	1,547.60	263
1933.....	990.96	166	1936.....	657.20	133
1934.....	1,773.46	317			

Gold.—The output of gold in Washington, in terms of recovered metal, was 12,217.40 fine ounces in 1936 compared with 9,739.60 ounces in 1935 and 8,301.83 ounces in 1934. Mines in Ferry County (chiefly in the Republic district) were the source of 57 percent of the total gold produced in Washington in 1936 and of 52 percent in 1935. The output of gold from Stevens County decreased decidedly in both 1935 and 1936 due to the closing of the First Thought mine at Orient, but that from Okanogan County increased sharply in both 1935 and 1936 due to the reopening of the Bodie mine near Wauconda. Gold ore yielded 94.33 percent and placers 5.38 percent of the total gold in 1936; crude ore of smelting grade yielded 51.09 percent of the total, concentrates of all classes 6.53 percent, and bullion from gold and silver mills 37.01 percent. There was a marked decrease in gold from small-scale placer mining in 1936.

Silver.—The output of silver was 66,900 fine ounces in 1936 compared with 52,338 ounces in 1935 and 44,120 ounces in 1934. Most of the silver produced in Washington comes from siliceous gold ore, and in 1936 the Mountain Lion and Aurum mines at Republic produced nearly half the total; silver ore, copper ore, and lead-zinc ore together yielded about 40 percent of the total. Crude ore of smelting grade yielded nearly 64 percent of the total silver in 1936 and concentrates of all classes about 29 percent.

Copper.—The output of copper in Washington was 204,000 pounds in 1936 compared with 86,690 pounds in 1935 and 13,900 pounds in 1934. The increases were due to the reopening in 1935 of the Royal mine near Leavenworth and the Sunset mine near Index, both pro-

ducers of copper ore. Nearly 79 percent of the copper produced in 1936 came from copper concentrates, and most of the remainder came from copper ore of smelting grade.

Lead and zinc.—The output of lead in Washington was 1,680,000 pounds in 1936 compared with 206,150 pounds in 1935 and 581,298 pounds in 1934. The output of zinc was 8,806,000 pounds in 1936 compared with 2,159 pounds in 1935 and 3,852,419 pounds in 1934. The marked decrease in the output of both lead and zinc in 1935 was due to the closing early in 1934 of the Josephine mine and mill of the Pend Oreille Mines & Metals Co., at Metaline Falls; the property was reopened in 1936 and yielded nearly all the lead and zinc produced. A little lead ore was marketed from the Electric Point and Gladstone Mountain mines near Northport in both 1935 and 1936, and a little lead-zinc ore was shipped from the Old Dominion mine near Colville in 1936; all three mines are in Stevens County.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Washington, 1935-36, by counties, in terms of recovered metals

MINING INDUSTRY

There were marked increases in the output of all five metals in Washington in 1936, and the total value of the output (\$1,015,771) was larger than that for any year since 1925. Nearly 84 percent of the increase in total value over 1935 was in lead-zinc ore and resulted chiefly from the reopening of the property of Pend Oreille Mines & Metals Co. at Metaline Falls. The gains in gold and silver output resulted chiefly from the increased activity at mines near Republic, and the increase in copper output came from the Royal mine near Leavenworth and the Sunset mine near Index.

Several new development projects begun or completed in 1936 were of especial interest to the mining industry in Washington. Of outstanding importance is the new 1,000-ton flotation plant at the Holden property, under construction early in 1937 by the Chelan Lake Division of the Britannia Mining & Smelting Co. Ltd., which when completed will be the largest milling plant in the State. The Knob Hill Mines, Inc., completed in April 1937 the construction of a new 400-ton all-slime cyanidation plant near Republic, Ferry County, and the American Smelting & Refining Co. completed and placed in operation in November 1936 a new cyanidation plant at the Azurite property in Whatcom County. Early in 1937 the Pend Oreille Mines & Metals Co. was building a 5,000-horsepower hydroelectric plant on the river below Metaline Falls; with the completion of the power

plant it is expected that the capacity of the Josephine mill will be increased from 300 to 600 tons daily. New activity was reported at many small lode-gold mines in Washington in 1936, but there was a marked decrease in work at small-scale placer properties.

Value of metals from ore sold or treated in Washington, 1935-36, by classes of ore

Class	Ore (short tons)	Gold	Silver	Copper	Lead	Zinc	Total value
1935

	133,435	404,607	51,711	18,768	77,280	440,300	992,666

Gold ore.—The output of gold ore in Washington was 44,786 tons in 1936 compared with 27,978 tons in 1935 and 17,456 tons in 1934. Most of the increase in 1936 came from mines at Republic and from the Bodie mine near Wauconda. Of the total gold ore produced in 1936, nearly 43 percent (19,176 tons) was ore treated at amalgamation and concentration mills and nearly 41 percent (18,279 tons) was crude ore of smelting grade; in addition, 5,931 tons were cyanided, 500 tons were amalgamated, and 900 tons were concentrated. Mines in Ferry County produced 45 percent of the gold ore and those in Okanogan County 45 percent; most of the remainder came from Whatcom County.

Silver ore.—The decrease in output of silver ore in 1936 was due to the closing early in 1935 of the Deer Trail mine in the Springdale district, Stevens County; most of the output in 1936 came from the Silver Queen mine near Kettle Falls, Stevens County, and the Chloride Queen mine, Palmer Mountain district, Okanogan County.

Copper ore.—The output of copper ore was 11,993 tons in 1936 compared with 752 tons in 1935. All of the output in 1936 came from the Royal mine near Leavenworth and the Sunset mine near Index, and most of it was concentrated.

Lead ore.—All the lead ore produced in 1936 was of smelting grade; it came from four properties in Stevens County, including the Electric Point and Gladstone Mountain mines at Northport.

Lead-zinc ore.—The output of lead-zinc ore in Washington was 76,169 tons in 1936 compared with only 3 tons in 1935 and 28,322 tons in 1934. Most of the output in 1936 came from the Josephine mine of the Pend Oreille Mines & Metals Co. and was treated by flotation; the remainder came from the Old Dominion mine near Colville and was shipped to a custom mill near Kellogg, Idaho,

METALLURGIC INDUSTRY

The total output of ore in Washington in 1936 was 133,435 tons, comprising 89,164 tons treated at concentration plants, 25,607 tons treated at gold and silver mills, and 18,664 tons shipped crude to smelters.

The ore treated at gold and silver mills comprised 500 tons treated at nine small straight-amalgamation mills, 5,931 tons treated at three straight-cyanidation mills, and 19,176 tons treated at three combined amalgamation and gravity-concentration plants.

Five straight-concentration plants were operated in Washington in 1936 and treated 89,164 tons of ore—two plants treating siliceous ore, two treating copper ore, and one treating lead-zinc ore. Most of the ore concentrated was lead-zinc ore (76,169 tons) and copper ore (11,910 tons) treated by flotation. The following tables give production of concentrates by classes and counties.

The output of crude ore of smelting grade in Washington was 18,664 tons in 1936 compared with 15,296 tons in 1935 and 16,185 tons in 1934. Nearly all the ore smelted in 1936 was gold ore shipped from the Republic district to Tacoma for smelting. Small lots also of silver ore, lead ore, and copper ore were shipped to smelters.

CHELAN COUNTY

The Royal Development Co. resumed production at the Royal mine north of Leavenworth in 1935 and operated continuously during 1936. More than 10,000 tons of low-grade copper ore were treated in the 350-ton flotation plant during 1936. Copper concentrates are stored during the winter months; they are shipped to Tacoma for smelting.

The Chelan Lake Division of the Britannia Mining & Smelting Co., Ltd., resumed development in May 1936 at the Holden mine about 50 miles northwest of Chelan; the mine is reached by boat from Chelan to Lucerne and by road from Lucerne. Extensive diamond drilling has been completed at the mine, and during 1936 a large crew was driving the lower adit. Early in 1937 the company let contracts for the construction of a flotation plant, a 50-mile power line, docks, barges, and other equipment necessary for operation on a 1,000-ton-daily basis. About 1 year will be required to complete the present construction program.

FERRY COUNTY

Republic district.—Siliceous gold ore from mines near Republic in 1935 and 1936 represented, as usual, a substantial part of the State's total metal production. The output of the Republic district was valued at \$173,116 in 1935 and at \$264,194 in 1936. The chief producers in 1935 were the Aurum and Blaine Republic mines and in 1936 the Mountain Lion, Aurum, Quilp, and Morning Glory mines. The Blaine Republic mine and cyanide mill were closed early in 1936. The Eureka M. & M. Co. was formed during 1936 to operate the Quilp property; the company also has a 10-year lease on the Blaine Republic property, and in November and December 1936 ore from the Quilp mine was being treated in the 60-ton cyanidation mill on the Republic property. Ore from the Mountain Lion, Aurum, and Morning Glory mines was shipped for smelting. No production during 1936 was reported from the Knob Hill mine.

Diamond drilling was completed on the Mud Flat claim (part of the Knob Hill group), and the Knob Hill Mines, Inc., was formed in 1936 to acquire the property and erect a new 400-ton cyanidation plant. Construction was delayed by severe winter weather, but in April 1937 the new all-slime plant was completed.

Other districts.—Other production from Ferry County in 1935 and 1936 included gold ore from the Morning Star mine near Danville and placer bullion from various bars on the Columbia River.

KITITAS COUNTY

Small lots of rich gold ore from several mines (including the Mountain Daisy, Liberty, and Morris) near Liberty were treated by amalgamation in both 1935 and 1936; most of the placer output came from the Burcham and Sunny Bar properties. A new sluicing plant was built in 1936 at the Boulder placer of the Salem Mining Co., but operations were discontinued and the plant was dismantled after a short run.

OKANOGAN COUNTY

The Northern Gold Corporation was formed in 1935 to operate the Bodie mine 12 miles north of Wauconda. The company rebuilt the milling plant (70-ton amalgamation and gravity-concentration) and in 1935 treated about 9,000 tons of ore, shipping bullion and rich gold concentrates. The production was doubled in 1936 when nearly 19,000 tons of ore were milled. Other producing lode mines in Okanogan County in 1936 included the Golconda mine near Wauconda, the Red Shirt mine near Twisp, the Gray Eagle and Peterson properties near Chesaw, the Chloride Queen mine near Nighthawk, and the Spokane and Owasco properties near Oroville. Placers were operated in 1936 along the Columbia, Similkameen, and Twisp Rivers and on Myers and Mary Ann Creeks.

PEND OREILLE COUNTY

Metaline district.—The Pend Oreille Mines & Metals Co. suspended production at the Josephine property in April 1934, and no ore was mined or milled until operations were resumed in 1936, when the company milled 76,060 tons of lead-zinc ore in the new 300-ton flotation plant. Underground development at the Josephine mine was carried on continuously during the shut-down. The company also dismantled the old mill at the Josephine shaft and erected a new plant (salvaging some of the equipment from the old mill) at a site on the Cascade tunnel level. Early in 1937 the company was building a 5,000-horsepower hydroelectric plant on the river below Metaline Falls, and upon completion of the plant the milling capacity probably will be increased to about 600 tons a day.

The Metaline Mining & Leasing Co., controlled by the American Zinc, Lead & Smelting Co., made no production in 1936, but a large tunnel crew was employed from May 1 until the end of the year in driving nearly 2,300 feet at the main haulage tunnel.

SNOHOMISH COUNTY

The Sunset mine at Index was operated from September 1936 to the end of the year by the Sunset Syndicate Corporation. Copper ore was treated in the 150-ton concentrator, and concentrates and some crude ore were shipped to Tacoma for smelting. Placer bullion was marketed from small-scale operations on the Sultan River.

STEVENS COUNTY

The First Thought mine near Orient, an important producer of gold in 1935, was closed early in 1936; a 50-ton cyanidation mill was being built at the property in 1936. Other producing lode mines in Stevens County in 1936 included the Electric Point and Gladstone Mountain properties near Northport and the Old Dominion property near Colville. Placer operations along the Columbia River yielded considerable gold in both 1935 and 1936.

WHATCOM COUNTY

The American Smelting & Refining Co. continued development work at the Azurite property in the Slate Creek district during 1935 and in November 1936 completed and placed in operation a 100-ton cyanidation plant; several thousand tons of ore were treated in the new mill before the end of the year. The Boundary Red Mountain mine in the Mount Baker district was formerly a large producer of gold in Washington; it was purchased in 1935 by the International Gold Mines, Ltd. Several hundred tons of ore were treated in 1935; in 1936 the operating season was disrupted by failure of the power plant, and only 200 tons of material were treated. Repairs were made, however, and the mill (amalgamation and concentration) was rebuilt; operations were resumed in 1937. Gold ore was also produced at the Whistler, New Light, and Tom, Dick, & Harry properties.

GOLD, SILVER, COPPER, AND LEAD IN WYOMING

(MINE REPORT)

By CHAS. W. HENDERSON and A. J. MARTIN

SUMMARY OUTLINE

	Page		Page
Summary.....	555	Review by counties and districts—Contd.	
Calculation of value of metal production.....	555	Carbon County.....	556
Review by counties and districts.....	556	Fremont County.....	557
Albany County.....	556	Park County.....	557

Lode and placer mines in Wyoming produced, in terms of recovered metals, 1,964.40 fine ounces of gold and 1,113 fine ounces of silver in 1936 compared with 3,715.00 ounces of gold, 1,152 ounces of silver, 1,000 pounds of copper, and 5,000 pounds of lead in 1935. The Atlantic City district, Fremont County, yielded nearly all the gold in 1936; the remainder (40.89 ounces) was contained in ore, amalgamation bullion, and placer dust shipped from scattered districts in Albany, Carbon, and Park Counties. The silver was a byproduct of gold mining, except the 839 ounces produced in the Kirwin district, Park County. There were 5 producing lode mines and 25 placers in 1936 compared with 10 and 38, respectively, in 1935.

The total recorded production of gold, silver, copper, and lead (in terms of recovered metals) in Wyoming from 1867 to 1936, inclusive, according to Chas. W. Henderson, has been 73,515 fine ounces of gold, 73,766 fine ounces of silver, 32,638,059 pounds of copper, and 16,800 pounds of lead.

Calculation of value of metal production.—The value of metal production herein reported has been calculated at the prices given in the table that follows. Gold in 1932 is figured at \$20.671835 per ounce, the Treasury legal coinage value for fine gold from January 18, 1837, to January 31, 1934; in 1933 at \$25.56 and in 1934 at \$34.95 per ounce, the yearly average weighted United States Government price¹; and in 1935 and 1936 at \$35 per ounce, under authority of the Gold Reserve Act of January 31, 1934. The silver price in 1932 and 1933 is the average New York price for bar silver; in 1934, the Treasury buying price (\$0.64646464+ per ounce) for newly mined silver; and in 1935 and 1936, the yearly average weighted Treasury buying price for newly mined silver. The copper, lead, and zinc prices are weighted yearly averages of all grades of primary metal sold by producers.

¹ The Treasury from Feb. 1, 1934, through December 1934 has calculated all gold, old and new, at \$35 per ounce, under authority of the Gold Reserve Act of Jan. 31, 1934. Details of the U. S. Government fluctuating price of gold in 1933 to Jan. 31, 1934, may be found in *Minerals Yearbook*, 1934, pp. 25-28.

REVIEW BY COUNTIES AND DISTRICTS

ALBANY COUNTY

The only output from Albany County in 1936 was 17 tons of dry gold ore shipped by the Star Mining Co. to the Garfield (Utah) smelter from a property in the Douglas Creek district. The Rare Metals Corporation drove 90 feet of development at its Electrolytic group, in the same district, from September 1 to December 31. Other properties at which development work was reported during the year were the New Deal group in the Albany district and the Cliff group and Commercial Gold Mining Co. property in the Centennial district.

CARBON COUNTY

A 7-ton stamp mill with amalgamation plates was run for a few months during the latter half of 1936 on ore from the Nellie F claim in the Gold Hill district, in secs. 15 and 16, T. 16 N., R. 80 W., sixth principal meridian; amalgamation bullion recovered was shipped to the Denver

Mint. The Golden Sun Mining Syndicate, Inc., did considerable development work from January 1 to August 1 at the Vulcan group near Encampment. Extensive testing was done during the summer months at the J. Phillips placer property in the Spring Creek area. Sluicing at the Working Boy placer on Savery Creek yielded several ounces of placer gold.

FREMONT COUNTY

Atlantic City district.—Two companies using dragline excavators and portable screening and sluicing equipment on placer ground in the Atlantic City district recovered 78 percent of the total output of gold in Wyoming in 1936. One of these, the largest producer, was the E. T. Fisher Co.,² operating on Rock Creek for its fourth season; it worked 200 days in 1936, as in 1935. The Fisher apparatus consists of a 1½-cubic yard dragline bucket and a screening-sluicing-amalgamation plant mounted on rail tracks and pulled ahead by the power of the dragline. The second largest producer was the Jett-Ross Mines, Inc., which operated on Big Atlantic Gulch from April 24 to September 15 with equipment similar to that of the E. T. Fisher Co. The Rigdon Mines Co. moved a dragline excavator and screening and sluicing equipment to the May Day-Megget placer in July but operated for a short period only. Small-scale sluicing operations by individuals yielded 81 ounces of gold.

The Iron Duke-Hidden Hand lode mine was operated during the first part of 1936 by the Iron Duke Mining Co. and later in the year by various lessees; the ore produced was sold to the Midvale (Utah) smelter. The Duncan mine was idle throughout the year; the only output was amalgamation bullion and concentrates recovered from clean-up operations at the mill. The Gold Dollar and Miners Delight groups were consolidated and operations under the new firm name of Miners Delight Consolidated Mines Co. were planned for 1937.

PARK COUNTY

Lessees at the Little Johnnie mine in the Kirwin district, about 70 miles southwest of Cody, shipped 13 tons of silver ore to the East Helena (Mont.) smelter in 1936.

Statistical summary of secondary metals recovered.....	559	Secondary tin.....	566
Scope of report.....	559	Secondary aluminum.....	568
Secondary copper and brass.....	562	Secondary antimony.....	569
Secondary lead.....	564	Secondary nickel.....	570
		Classification of old metals.....	571

The total value of certain nonferrous metals, for which the quantity recovered from secondary sources is reported to the Bureau of Mines, was \$174,183,300 in 1936, \$19,146,500 more than in 1935; the total quantity increased 58,785 short tons. The increase in total value was due partly to higher average prices for copper, zinc, and lead, but the recovery of secondary copper, zinc, tin, aluminum, antimony, and nickel also increased.

Secondary metals of certain classes recovered in the United States, 1935-36

Scope of report.—"Secondary metals" are those recovered from scrap metal, sweepings, skimmings, and drosses and are so called to distinguish them from metals derived directly from ores, which are termed "primary metals." The distinction does not imply that secondary metals are of inferior quality, for metals derived either from ore or from waste material vary in purity and in adaptability to use in making certain products. The figures furnished by producers cover seven metals—secondary copper, lead, zinc, tin, aluminum,

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

antimony, and nickel—and supplement those on the primary metals. They are given to enable producers and consumers to form a more comprehensive idea of the quantities of metal available for consumption; in fact, they constitute an essential complement to the figures in the general reports on the primary metals and will become more valuable in the future.

The variety of waste material (especially metallic wastes), its utilization, and much information on its collection and disposal appear in reports of this series for preceding years. These reports name the various trade papers that cover the subject of secondary metals and refer to many articles relating to secondary metals recovered.

Several papers² presented at the 1937 annual meeting of the National Association of Waste Material Dealers, Inc., dealt with the problems and needs of metal dealers and brokers in the scrap-metal industry.

SECONDARY METALS RECOVERED

The quantity of metals contained in numerous alloys made partly or wholly from secondary material cannot be ascertained definitely. The figures in the following tables and text, which are based upon results of the annual canvass, are approximate but constitute the only available data on an industry of growing importance.

Mints and refineries reported the recovery of 1,025,022 fine ounces of gold and 16,703,353 fine ounces of silver from waste or discarded material in 1936, compared with 1,668,305 ounces of gold and 35,903,107 ounces of silver in 1935. Jewelry and dental waste furnish the largest quantity of secondary gold and silverware and photographic waste the largest quantity of secondary silver.

No data are collected by the Bureau of Mines showing the quantity and value of old rails, pipe, machinery, and other equipment renovated for original use. Newspapers and trade publications show that an enormous quantity of such ferrous material is salvaged and reused.

In 1936 the price of heavy copper scrap ranged from 7.125 cents a pound to 9.375 cents, No. 1 composition scrap from 5.50 to 8.125 cents a pound, old zinc scrap from 2.56 to 2.92 cents a pound, cast aluminum scrap from 11.50 to 12.87 cents a pound, and heavy lead scrap from 3.69 to 4.89 cents a pound. The average daily and weekly quotations for many scrap metals and alloys can be found in the *Waste Trade Journal*, *Waste Trade Review*, *Metal Industry*, and *American Metal Market*. The price of old tin pipe ranged from 36.83 to 44.05 cents a pound and averaged 38.95 cents, but the quantity of tin pipe marketed is quite small.

The favorable feature of the spread in secondary-metal prices in 1936 was the fact that, except in a very few instances, prices were lowest at the beginning of the year and increasingly higher during the last part of the year, when the rapid advance in metal prices carried scrap and secondary-metal prices to proportionately higher levels.

Demand for secondary metals depends largely on general industrial conditions; hence the business improvement in 1936 reacted favorably on the secondary-metals trade. Foundries long inactive or operated at small capacity for several years absorbed large quantities of scrap or ingot made from waste metals, and the automotive industry purchased large quantities of secondary aluminum.

The quantity of scrap copper re-treated did not increase, and regular smelters treated less scrap copper in 1936 than in 1935. On the other hand, the quantity of brass scrap remelted increased about 50,000 tons. The decrease in production of secondary lead as metal was much greater than the increase in lead recovered in alloys. Probably some scrap copper and scrap lead were being held by dealers who expected increases in prices, and large sales that would increase profits in the last 2 months of 1936 probably were not desired. The increase in the price of copper will permit shipment of considerable low-grade foundry ashes and skimmings which it has been impossible to market at any price for several years.

A number of medium-size secondary smelters did not sell to ultimate consumers in 1936 but shipped their output to large secondary-metal interests having steady large outlets for materials. On the whole, 1936 was a moderately successful year for most dealers and smelters of secondary metals, and prospects are that 1937 will be a most prosperous year.

There were few important failures in the trade and few new small enterprises. The general tendency is toward greater concentration of the secondary-metal business in the hands of the large operators and interests that deal largely in primary metals.

During the past 2 years the Bureau of Mines has made surveys of consumption of scrap iron and scrap steel.³ Consumption of home scrap totaled 18,860,000 gross tons in 1936 compared with 13,347,000 tons in 1935 and that of purchased scrap, 17,609,000 tons in 1936 compared with 13,069,000 tons in 1935. Details as to type of furnace in which the scrap was charged and geography of ferrous-scrap consumption were also presented.

Legislation directly concerned with the secondary-metal industry in 1936 comprised the law (Public, No. 448, 74th Cong.) requiring that no exports of tin-plate scrap be made from the United States without a license, obtainable now under certain conditions from the Secretary of State. This was described in the Secondary Metals chapter of Minerals Yearbook, 1936, and is referred to in the Secondary Tin section following.

Proposed legislation in 1937 which is of considerable concern to the scrap and secondary-metal industry comprises a bill (H. R. 6322) to provide for cooperation between the United States and foreign nations producing tin ore and other materials to assure to the United States continuing supplies thereof to supplement deficient domestic resources and production, and for other purposes, and a bill (S. 2025) to provide for the protection and preservation of domestic sources of scrap steel.

The former bill would set up a Board for Strategic Materials which would recommend to the President after careful studies what materials should be classified as strategic; the President would then be em-

³ Lund, R. J., and Davis, H. W., Consumption of Ferrous Scrap and Pig Iron in the United States in 1935: Rept. of Investigations 3329, Bureau of Mines, 1936, 14 pp.

Ridgway, R. H., Davis, H. W., and Trought, M. E., Consumption of Ferrous Scrap and Pig Iron in the United States—1936: Min. Market Rept. M. M. S. 550, Bureau of Mines, May 28, 1937.

powered to declare by Executive order such materials strategic. The Board further would be authorized to study, devise, and suggest ways and means for cooperation between the United States and countries producing strategic materials; it would be authorized to make studies, surveys, tests, etc., for the purpose of developing resources of such materials in the United States or of finding substitutes therefor. Other sections of the act call specifically for an extensive survey of the United States, Alaska, and Hawaii for the purpose of locating and testing possible tin ores and for comprehensive studies on the development of substitutes for tin.

The latter bill, the so-called Schwellenbach bill, would require the licensing of all exports from the United States and Territories of steel-plate scrap.

Another bill, submitted later by Senator Austin, of Vermont, in the form of a resolution, would prohibit exports of iron and steel scrap (including all materials heretofore or hereafter classified as such in official publications of the Bureau of Standards) except upon license issued by the President of the United States.

A bill (H. R. 6621), proposing an amendment to the tin-plate licensing bill of 1936 to include other scrap containing tin together with drosses was still in committee late in May 1937.

Members of the waste-trade industry generally are strongly opposed to these possible export restrictions, and they point out that the high prices for ferrous scrap (which softened materially toward midyear of 1937) actually result in making huge supplies of this material available for use which otherwise would rust away because it could not stand freight charges to consumption or export centers. They also ask why scrap iron and steel should be singled out for export embargoing, when other basic raw materials important in rearmament uses are allowed unrestricted flow. Late in May it was reported * that Secretary of State Hull had expressed his opposition to the Schwellenbach bill in letters to the chairman of the Senate and House Military Affairs Committees, pointing out that an interdepartmental committee after careful consideration has "unanimously reached the conclusion that the export movement of scrap has created no emergency situation and that there is no actual or prospective shortage of scrap" * * * and "that the disadvantages of direct or indirect restrictive action would outweigh the possible advantages."

Secondary copper and brass.—The copper produced in 1936 by smelters of secondary material only includes 127,085 tons of pig copper (part of which was electrolytically refined), 119,300 tons of copper in remelted brass, and 105,300 tons of copper in alloys other than brass. These figures indicate increases of 5,557 tons in pig copper, 34,700 tons in copper in brass, and 11,000 tons in copper alloys other than brass. Regular copper smelters produced 15,563 tons less secondary copper in 1936 than in 1935.

The total value of secondary copper as metal and in brass and other alloys, computed at 9.2 cents a pound (the average price in 1936 of all merchantable grades of new metal), was \$89,166,400, about \$14,649,000 more than in 1935.

Imports of brass scrap decreased from 119 tons in 1935 to none in 1936, and those of copper scrap increased from none in 1935 to 754 tons in 1936. Brass scrap exported decreased 17,453 tons, and copper scrap exported, increased 3,677 tons.

* Daily Metal Reporter, May 26, 1937, p. 10.

Secondary copper recovered in the United States, 1935-36 and imports and exports of brass and copper scrap, in short tons

	1935	1936		1935	1936
Copper as metal.....	1270,000	1260,000	Total secondary copper (including copper content of brass scrap):		
Copper in alloys other than brass.....	94,300	105,300	From new scrap.....	87,200	101,900
	364,300	365,300	From old scrap.....	361,700	382,700
Copper from new scrap (not including brass).....	45,000	40,000		448,900	484,600
Copper from old scrap (not including brass).....	319,300	325,300	As metal.....	270,000	260,000
	364,300	365,300	In brass and other alloys...	178,900	224,600
Brass scrap remelted:				448,900	484,600
New clean scrap.....	60,000	88,400	Brass scrap imported.....	119	754
Old scrap.....	60,800	82,000	Scrap copper imported.....		
	120,800	170,400	Brass scrap exported.....	29,792	12,339
Copper content of brass scrap (averaging 70 percent copper):			Scrap copper exported.....	9,547	13,224
New scrap.....	42,200	61,900			
Old scrap.....	42,400	87,400			
	84,600	119,300			

¹ Of these totals secondary copper reported by smelters and refiners that treat mainly primary metal comprised 148,478 tons in 1935 and 132,915 tons in 1936.

The terms "new brass scrap" and "new copper scrap", as applied in the preceding table, refer to the scrap that is accumulated in fabricating products; "old scrap" is the metal that was made into products and after service has been discarded and returned to be remelted or refined for further use. Few junkmen, dealers, or smelters keep any statistics of "old scrap" and "new scrap". Most of the new scrap is clippings, grindings, and defective articles made in the ordinary operations in fabricating goods, some of which is reused at the plant and the remainder sold. All foundries (many of which purchase scrap metals) are advised in the Bureau of Mines questionnaire to exclude all scrap made and used in their own plants and to give data solely on purchased scrap. Those that purchase only "new scrap" of certain grades and assay can give correct data; the others usually can make no distinction between "new" and "old" scrap. Secondary smelters usually cannot give exact figures but occasionally can estimate the proportion of "new" scrap metal treated. The figures in the preceding table are the best obtainable.

Reports for 1936 show that railroads reused at their shops and foundries the following quantities of scrap metals: 7,800 tons of brass; 1,020 tons of copper; 11,108 tons of copper in alloys other than brass; 1,400 tons of tin in babbitt, solder, and bronze; and 4,980 tons of lead in various alloys.

Apparently stocks of scrap copper and copper alloys are normal at large dealers' yards, smelters, and foundries. The pick-up by small collectors remote from smelters increased to some extent during the last 3 months of 1936. Urban collections from fabricating plants usually were marketed quickly.

The use of various alloys (ordinarily in small quantities) in the manufacture of brass is becoming more prevalent. It is thought that purchasing agents will be required to specify more closely in order to obtain the type of metal desired.

Secondary lead.—The output of secondary lead in 1936 equaled 66 percent of the total production of refined primary lead from domestic and foreign sources in the United States, compared with 83 percent in 1935. Much recovered lead is derived from discarded batteries, pipe, sheet, and lead-covered cable; other sources are solder, babbitt, and shot.

Secondary lead recovered by smelters whose product is mainly primary metal decreased 10,192 tons in 1936. The output of pig lead by secondary smelters decreased about 9,108 tons, and that of lead in scrap alloys increased 8,349 tons.

Old batteries were collected in 1936 at a rate equal to that in 1935. Collections were good in urban but only fair in rural areas. In the closely populated areas apparently dealers did not accumulate battery plates or old batteries but unloaded them as fast as purchased, so that scrap batteries available were those actually taken in current trade. The higher price of lead now prevailing doubtless will increase the quantity of old batteries marketed from midwestern and mountain areas, although this will not add appreciably to the smelter receipts. Recovery of battery plates will increase in 1937 owing to the increased scrapping of old cars.

Secondary lead recovered in the United States, 1935-36, in short tons

	1935	1936
Secondary lead recovered by smelters that treat mainly ore.....	44,748	34,556
Secondary lead recovered by smelters that treat only scrap and drosses.....	112,052	102,944
	156,800	137,500
Secondary lead recovered in remelted alloys:		
Estimated secondary lead content of antimonial lead produced at regular lead smelters ¹	9,479	12,930
Lead content of drosses and scrap alloys treated at secondary smelters.....	104,121	112,470
	113,600	125,400
Total secondary lead recovered.....	270,400	262,900

¹ Antimonial lead produced at primary smelters totaled 16,384 tons containing approximately 4,685 tons of primary domestic lead, 491 tons of primary foreign lead, 1,110 tons of primary domestic antimony, 26 tons of primary foreign antimony, 9,479 tons of secondary lead and 593 tons of secondary antimony in 1935, compared with 23,230 tons containing approximately 7,442 tons of primary domestic lead, 696 tons of primary foreign lead, 1,434 tons of primary domestic antimony, 37 tons of primary foreign antimony, 12,930 tons of secondary lead, and 691 tons of secondary antimony in 1936.

Refined primary lead produced in the United States, 1935-36, in short tons

	1935	1936
From domestic ore.....	310,505	387,098
From foreign ore and base bullion.....	14,055	11,458

A number of secondary smelters treating old batteries and other lead alloys now recover much of the lead as good-grade pig lead. The residues and drosses containing antimony are then used in making hard lead containing various percentages of antimony.

Some of the problems in handling old batteries are stated in an article by Neuman.⁵

⁵ Neuman, E. A., *Journey of Battery Plates from Dealer to Consumer*: Waste Trade Jour., Mar. 27, 1937, pp. 89, 94.

The question of the prices paid for battery plates is discussed in an article by Schoenback.⁶

The sampling of battery plates is much more difficult than the assaying, due to the moisture in the rubber and separators.

A large number of the old batteries are smelted on toll by custom smelters. The smelters also purchase batteries at a price based on that of pig lead at St. Louis, the antimony content being paid for at the price of lead, although the price of antimony in 1936 was about three times that of lead.

Secondary zinc.—Secondary zinc recovered as pig metal and in alloys (including brass) increased 27,750 short tons, largely in redistilled zinc and zinc in brass. The zinc content of brass remelted was 12,600 tons more in 1936 than in 1935. The total recovery of secondary zinc (including that in brass) equaled 25 percent of the total output of primary slab zinc in the United States (492,132 tons) in 1936. In addition, large quantities of the zinc dust, zinc chloride, and other compounds were made from zinc drosses and residues.

Secondary zinc¹ recovered in the United States, 1935-36, and products made from zinc dross, skimmings, and ashes, in short tons

¹ Figures do not include scrap and dross used for lithopone or chloride. The use for zinc chloride, especially, is large.

² Revised figure.

³ Figures not available.

Zinc recovered by redistillation increased from 28,650 tons in 1935 to 42,209 in 1936. Of the 1936 total, 22,142 tons (an increase of 8,703 tons) were recovered at primary smelters from zinc drosses and 20,067 (an increase of 4,856 tons) at five secondary plants using large graphite retorts and two plants using clay retorts, which treated only drosses and residues in 1936. The five active smelters using large graphite retorts in 1936 were:

Federated Metals Corporation, Trenton, N. J.
 General Smelting Co., Philadelphia, Pa.
 Nassau Smelting & Refining Co., Tottenville, N. Y.
 Superior Zinc Corporation, Bristol, Pa.
 Wheeling Steel Corporation, Wheeling, W. Va.

Of the total output of 163,340 tons of lithopone in 1936, 67,361 containing 13,450 tons of zinc were made from zinc skimmings and ashes.

⁶ Schoenback, Walter, *Pyramiding Battery Plate Prices*: Waste Trade Jour., Mar. 23, 1936, p. 97.

The American Bureau of Metal Statistics estimates that 242,000 tons of zinc (47,000 more than in 1935) were used in 1936 in zincking (galvanizing) sheets, forms, tubes, wire, and other materials.

Secondary tin.—Secondary tin recovered amounted to 28,020 tons valued at \$25,621,500 in 1936, compared with 27,900 tons valued at \$27,498,200 in 1935. The total value assigned is based on the yearly average price (45.72 cents in 1936 and 49.28 cents in 1935) given by the American Metal Market for 99-percent metal, prompt delivery at New York.

The 1935 and 1936 figures for recovery of pig tin are not comparable, as in 1936 it was decided to eliminate from secondary-tin figures all tin recovered at tin-plate plants by operators by treating tin scruff. This tin is recovered in the ordinary course of operations at nearly all plants, and its elimination decreased 1936 totals about 2,000 tons. The tin recovered in 1936 in alloys and chemical compounds increased 2,470 tons. Secondary tin recovered in 1936 was equivalent to about 33 percent of the tin imported into the United States as pig metal in 1936.

According to the American Iron and Steel Institute 2,355,561 long tons of tin plate and terneplate were made in 1936. It is estimated that about 40,000 long tons (an increase of 25 percent) of tin were used in these products and that 4,265 short (3,808 long) tons of tin were recovered from tin-plate clippings and old coated containers.

Owing to the relatively high value of tin, it is important that the degree of accuracy be high in obtaining representative samples of shipments of tin dross and in analyzing them later.⁷

Many earlier chapters of this series contain data on plants and processes followed, and a complete history of the different methods of detinning has been published by Mantell.⁸

Under the Act of Congress passed February 1936, "To provide for the protection and preservation of domestic sources of tin", and the subsequent Executive order issued by the President of the United States, it is necessary to obtain a license from the Secretary of State for all exports of tin-plate scrap. According to a press release of the Department of State, January 4, 1937, the Department received applications for license to export 23,383 long tons of tin-plate scrap between July 1 and December 31, 1936. Forty-nine licenses, authorizing the exportation of 6,483 long tons of tin-plate scrap valued at \$106,854, were issued during that period. All of these licenses were for export to Japan.

Allotments have been assigned to 39 producers for export of 18,609 long tons of tin-plate scrap, subject to license, during the early part of 1937; applications for allotments in 1937 have totaled 27,752 long tons.

An amendment to the act has been proposed requiring an export license for shipping tin-plate scrap to Hawaii and Puerto Rico to prevent reexportation to ultimate consumers. The waste-material industry is much disturbed over the proposed embargo on scrap-iron and steel exports and over a bill introduced on April 12, 1937, which seeks to provide for cooperation between the United States and foreign nations producing tin ore and other materials "to assure the United States continuing supplies of the same to supplement deficient domestic resources and production, and for other purposes." The industry

⁷ Kasey, J. B., A Suggested Method of Preparing Deliquescent Tin Dross Samples: *Met. Ind.*, September 1936, p. 338.

⁸ Mantell, C. L., Scrap Detinning Affords Big Outlet for Chlorine: *Chem. and Met. Eng.*, 1926, pp. 477-479.

does not like the words "for other purposes." It feels that the restrictions on the export of tin-plate scrap may be extended to all scrap containing even small quantities of tin, as provided for in a bill (H. R. 6621, 75th Cong. 1st sess.) still in committee late in May, and perhaps to scrap containing antimony, nickel, chrome, cobalt, and other so-called strategic metals.

The proposed embargo on iron and steel scrap would affect the export of various alloy steels that contain metals not mined in the United States in sufficient quantities to supply domestic uses.

Although the average yearly price of tin declined, it remained close to 46 cents a pound in 1936 and resulted in the detinning of old tin-coated containers (about 3,300 tons) for the third time in many years. The old cans yield much less tin than clean tin-plate clippings. Many more old cans will be treated at the plants now equipped to handle them, but the high cost of collecting and shipping them militates against their use. There are also the additional costs of cleaning and handling bulky material. Thus the use of old tin-coated containers probably will be confined to areas adjacent to the detinning plants.

Tin (metal) and tin concentrates (tin content) imported into the United States, 1935-36, in short tons

	1935	1936
Tin imported as metal.....	71,969	85,153
Tin concentrates (tin content) imported.....	199	200

The quantity of tin-plate clippings treated at detinning plants increased about 34,600 long tons in 1936, and the average cost of such clippings delivered at plants increased from \$14.73 a long ton in 1935 to \$14.80 in 1936. These clippings were treated at plants of the Vulcan Detinning Co. at Sewaren, N. J., Neville Island, Pa., and Streator, Ill.; of the Johnston & Jennings Co. of Cleveland, Ohio; and of the Metal & Thermit Co., at South San Francisco, Calif., East Chicago, Ind., and Chrome, N. J.

Imports of tin-plate scrap in 1936 totaled 9,873 long tons valued at \$94,049, compared with 9,185 tons valued at \$68,109 in 1935. Of these amounts, Canada supplied 9,275 tons valued at \$89,247 in 1936 and 8,794 tons valued at \$65,581 in 1935. Cuba supplied the remainder in both years.

Exports of tin-plate scrap decreased from 34,928 long tons valued at \$749,604 in 1935 to 14,375 valued at \$282,214 in 1936. Japan took about 91 percent of the total in 1935 and about 95 percent in 1936. The total quantity exported in 1936 after the export ban and licensing provisions became effective (Apr. 14, 1936) was 5,550 long tons, according to monthly export statistics published by the Bureau of Foreign and Domestic Commerce. This material would yield Japanese detinners about 35 pounds of tin per long ton.

Exports of waste tin plate increased from 24,525 long tons valued at \$1,449,008 in 1935 to 44,621 tons valued at \$2,635,662 in 1936, of which Japan took about 85 percent in 1935 and about 77 percent in 1936.

The tin reported recovered in alloys and compounds in 1936 included the tin content of products made from clean tin-plate scrap. Most of the tin recovered at the plants listed was in tin bichloride, tin crystals, tin tetrachloride, and tin oxide.

The total recovery of tin as metal or in compounds from clean tin-plate scrap in 1936 was 4,265 short tons, whereas it is estimated that makers of tinplate andterneplate consumed nearly 45,000 short tons of tin. Some old tin-coated containers treated at Sewaren, N. J., yielded 27.76 pounds of tin per long ton.

A plant in Los Angeles collected old cans locally for use in shredded scrap to precipitate copper from mine waters, but there was no attempt to recover the tin coating.

A book by C. L. Mantell, of Pratt Institute, Brooklyn, N. Y., entitled "Tin: Its Mining, Production, Technology, and Application", includes chapters on the sources of secondary tin and the various methods of detinning tin-plate scrap.

Secondary aluminum.—The recovery of secondary aluminum, including that in alloys, totaled 51,500 short tons valued at \$19,055,000, compared with 51,400 tons valued at \$19,018,000 in 1935. The values in both years were computed at 18.5 cents a pound.

The value of primary aluminum produced in the United States increased from \$22,070,000 in 1935 to \$41,612,000 in 1936 owing largely to an increase of about 88 percent in output.

Secondary aluminum recovered in the United States, 1935-36, in short tons

	1935	1936
Secondary aluminum recovered unalloyed.....	23, 500	20, 900
Aluminum recovered in alloys (mainly No. 12).....	27, 900	30, 600
	51, 400	51, 500

Primary aluminum produced in the United States and imported and exported, 1935-36, in pounds

	1935	1936
Primary aluminum produced in the United States.....	119, 295, 000	224, 929, 000
Aluminum (crude and semicrude) imported for consumption.....	21, 291, 235	25, 562, 571
Aluminum (crude and semicrude) exported.....	3, 970, 347	1, 605, 753

The spread in scrap-aluminum castings was 1.37 cents a pound in 1936; the demand was usually good, and the quantity available was cleaned up fairly well. Aluminum cylinder heads and aluminum-alloy pistons were used more extensively in motorcars than formerly, so that an increased quantity of scrap aluminum was consumed in the automobile industry. Scrap cast aluminum and old crankcases were in good demand and were somewhat scarce at times. Scrap-aluminum clippings remelted in the ordinary course of shop practice were excluded wherever possible from 1936 recoveries. Nearly 600 tons of aluminum clippings were used in making powdered aluminum in 1936.

Numerous alloys containing aluminum contribute to the secondary aluminum recovered, but No. 12 (a mixture of about 92 percent aluminum and 8 percent copper) constitutes the largest supply of material for remelting and refining. Other alloys are used in smaller quantities. Many automobile aluminum crankcases are sold to foundaries and do not reach the secondary smelters.

The approved standard methods of sampling and analyzing aluminum and its alloys are described in a pamphlet published by the Aluminum Research Institute in July 1932. A book⁹ by Anderson is interesting to smelters and users of secondary aluminum.

Prices for scrap cast aluminum ranged from 11.50 cents a pound in August to as high as 12.87 cents in December.

New aluminum clippings ranged in price from a low of 13.25 cents in July to a high of 14.25 cents in January; the average price in 1936 was only 0.46 cent higher than in 1935.

Secondary antimony.—The principal materials refined or remelted that contained antimony as an alloy were hard-lead drosses, babbitt, bearing metal, battery plates, pewter, and type metal. The antimony used in the pigment, paint, and ceramic industries is so dissipated that no secondary recoveries can be made, but a large proportion of the production of metal containing antimony returns in a few months or a few years for refining and reuse. Antimony in type metal and in bearings returns very rapidly for refining. This large return of scrap in type and bearing metals normally goes to the makers of type and bearing alloys, which restricts the market for antimonial lead. It may take several years for antimony in battery plates to return as scrap, but probably 85 percent is certain to come back for reuse.

The production of secondary antimony in the United States, most of which was recovered in alloys, increased in 1936. The average price for ordinary brands (Chinese grade) of antimony, as stated by the American Metal Market, was 12.97 cents a pound in 1936 compared with 14.08 cents in 1935. Smelters that ordinarily use primary ores, concentrates, or metal reported 1,471 tons of primary antimony and 691 tons of secondary antimony as contained in 23,230 tons of antimonial lead. The recovery of secondary antimony by secondary smelters increased about 200 tons.

Imports of antimony in ore, as metal, or in oxide were 6,304 tons more than in 1935.

Secondary nickel.—The nickel reported as recovered from secondary sources includes nickel in Monel metal (the natural alloy) but not that in ferrous alloys. The practice of using small quantities of nickel in iron and steel as well as in brasses and bronzes expanded greatly in both 1935 and 1936. Activity was much greater at foundries in 1936, and a large part of their products contained some nickel.¹⁰

Nickel was often substituted for tin to lower costs in certain alloys requiring tensile strength and ductility.

Most of the secondary nickel recovered in 1936 came from scrap-nickel anodes, nickel-silver, copper-nickel alloys, and Monel metal. Exports of nickel scrap and scrap alloys containing nickel increased. It is impossible to give the nickel content of all the exports of such nickel-bearing scrap, but the total nickel content reported by exporters who submitted data to the Bureau of Mines was 1,262 tons in 1936 and 960 in 1935.

The secondary nickel recovered in ferrous alloys was undoubtedly much larger in 1936 than in 1935. It is estimated by Robert C. Stanley, president of the International Nickel Co., Ltd., that about 42 percent of all nickel consumed in the United States is used in nickel iron and steel, mainly in motor cars, railway equipment, heat-resistant alloys, and machinery. All these industries expanded greatly in 1936.

Probably more secondary nickel is recovered from ferrous than from nonferrous alloys, but no figures are available. Certain alloys give uninformed dealers trouble.¹¹

Scrap iron and steel dealers are frequently careless in handling alloy ferrous scrap, and certain discarded equipment and automobile scrap which contain nickel are thrown in with the regular steel scrap instead of being kept separate and advantage taken of their greater value.¹²

Considerable information as to the composition and uses of nickel, Monel metal, and other nickel alloys is given in Inco and in special pamphlets on nickel and its various alloys, publications of the International Nickel Co. This company purchases nickel scrap and Monel scrap.

CLASSIFICATION OF OLD METALS

The classification of old metals drawn up by the Metals Division of the National Association of Waste Material Dealers, Inc., Times Building, New York, N. Y., and changed from time to time as desirable, is the standard of both dealers and manufacturers in the United States. The latest classification (Circ. M), effective March 16, 1932, was given in the Secondary Metals chapter, Minerals Yearbook, 1936. No immediate changes are contemplated in this classification.

There is a growing demand for scrap-metal specialties (not specifically covered by the classification), such as nickel alloys, German silver, Monel metal, cadmium, and molybdenum. Difficulties have arisen in making shipments to buyers' specifications, and with the object of eliminating some of the trouble the Waste Trade Journal published classifications used by one of its advertisers. A list of these was given on pages 338 and 339 of the Secondary Metals chapter in Mineral Resources of the United States, 1930, part I.

IRON ORE, PIG IRON, FERRO-ALLOYS, AND STEEL

Preliminary data indicate that world production of steel established a new high level in 1936, and that the output of pig iron, with an increase of 23 percent over 1935, was topped only by the record figure for 1929. Requirements accumulated from preceding depression years, together with the almost frantic armament race under way among the principal world powers, have imposed enormous demands upon the iron and steel industries. Of the total world output of pig iron and steel in 1936, the United States furnished about 34 and 40 percent, respectively.

In 1936 the American iron and steel industry increased its annual output for the fourth successive year; in fact, the production of steel and pig iron rose 40 and 45 percent, respectively—much larger relative gains than in 1935. The increase in domestic output of steel and of pig iron in 1936 over 1935 was greater than the total production in 1932. This larger output, which gained momentum during the year, required 61 and 68 percent, respectively, of the potential capacity. At the close of 1936 operations were definitely on a larger scale than

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

during the opening months, as the average rate of production in the first quarter was only 55 percent of capacity. The higher rate of operation reacted to the benefit of producers of such mineral products as iron ore, manganiferous iron ore, fluorspar, fluxing stone, and coke, which depend on the iron and steel furnaces for their chief market. Domestic production of iron ore, the principal raw material, increased 60 percent over 1935, and totaled 48,788,745 gross tons in 1936. The trends in domestic production of iron ore, pig iron, and steel for more than half a century are illustrated in figure 31.

¹ Includes a small quantity of ore produced in southern Wisconsin.² Figures not available.³ Some open pit included with underground.⁴ Some hematite included with magnetite.⁵ Some brown ore included with hematite.

The automotive industry in 1936, with an output of 4,454,535 cars, the largest since 1929, remained the chief consuming outlet for steel, taking one-fifth of the total output compared with one-fourth in 1935. Despite the increased farm income, relative and actual amounts of steel moving into agricultural outlets declined in 1936. Although the relative amount of steel going into containers dropped, consumption in this outlet increased moderately.

Revival in the capital-goods industries was paced by the increased proportion of steel absorbed by these industries. Demand by the railroads for larger amounts of steel was most striking in 1936, but the volume so consumed was still far less than in the twenties. The strict economy practiced by the railroads during the depression built up a back log of orders that is now being tapped. The demand not only includes materials needed to replace worn-out or scrapped equipment but also to build the new, high-speed, streamlined units for passenger service, necessitated by keen competition with other railroads as well as with motor and airplane transportation. For example, new, 12-car, stainless-steel, streamlined, air-conditioned trains make the run of 1,035 miles between Chicago and Denver in 16 hours.

The construction industry, though still lagging, took relatively more steel in 1936 than in 1935. A sharp increase in industrial construction was noted during the year. Residential building also advanced substantially but still remained far below the predepression level. The amount of steel consumed in machinery and highway construction likewise increased in 1936.

General price advances were noted during 1936, particularly for the fourth quarter, when there was a large volume of buying. At the end of the year the composite price of finished steel, as compiled by Iron Age, was 2.330 cents a pound, which was higher than the 1929 peak of 2.317 cents per pound. The prices for the various grades of pig iron advanced during the last 2 months of the year, but that for spiegeleisen remained steady. The price of ferromanganese, which dropped \$10 a ton to \$75 a ton in January as a result of the lower tariff under the trade agreement with Canada, was increased \$5 a ton in November. A particularly interesting development during 1936 was the adoption of a system of open-price announcements by the steel industry. Under this arrangement, the seller announces prices to the customer and agrees to notify him of any change. Open prices were in effect under the N. R. A. Steel Code, but when the code was abandoned the industry reverted to its former practices. Recent Federal legislation forbidding discrimination in prices to customers is expected to aid in maintaining open prices.

FIGURE 32.—Trends in prices of iron ore, pig iron, finished steel, and steel scrap, 1889-1936. The prices of iron ore and pig iron are the averages f. o. b. mines and furnaces, respectively, as reported to the Bureau of Mines; the price of finished steel is an average composite computed by American Metal Market; that of steel scrap is an average at Pittsburgh of No. 1 Heavy Melting computed by Iron Age.

Employee relationships in recent years have received more attention from managers of steel-producing industries. The number of employees increased materially during 1936 and exceeded that in 1929. Despite extensive mechanization, more man power is required to produce the great variety of finished steels now demanded. Vacations with pay for millworkers were instituted recently by many companies, and increases in wage rates were noted during the year.

Considerable new capacity was added to producing plants in 1936, and it is planned to add more in 1937. Such additional capacity was largely in the finishing end of the steel processes to meet the increased demand for certain types of products and to correct overbalanced capacity in other lines. Eight new open hearths were added in 1936, but no new blast furnaces were built, although several were remodeled

and enlarged. In fact, no new blast furnaces have been built since 1928, and many obsolete stacks have been dismantled and scrapped.

Imports of iron ore and pig iron into the United States were higher in 1936, and exports of iron ore decreased slightly. Exports of pig iron, which are very small, increased. Imports of ferro-alloys increased in 1936 over 1935, and exports, which are relatively unimportant, also were larger. Increases were noted in exports of a wide range of steel products, particularly tin plate, but scrap shipments abroad were slightly lower. Imports of steel products, which are relatively small, increased, and imports of scrap doubled.

Tariff changes.—Changes in the import duty on a number of iron and steel products have been made during 1935 and 1936 under the Trade Agreements Act of June 12, 1934. Such charges will be found in the Swedish Agreement effective August 5, 1935, the Canadian Agreement effective January 1, 1936, the Swiss Agreement effective February 15, 1936, the Belgian Agreement effective May 1, 1935, and the French Agreement effective June 15, 1936.

CONSUMPTION OF FERROUS SCRAP AND PIG IRON

Domestic consumption of iron and steel scrap totaled 36,469,000 gross tons in 1936, an increase of 38 percent over the 26,415,330 tons consumed in 1935, while pig-iron consumption in 1936 was 29,778,000 tons, or 44 percent more than in 1935, when 20,620,463 tons were consumed. Preliminary statistics given herein for the consumption of ferrous materials in 1936 are based on reports from concerns that use over 95 percent of the total consumption.

Of the 1936 total, 18,860,000 gross tons were home scrap and 17,609,000 tons purchased scrap. As employed in this report, the term "home" or "plant" scrap refers to scrap produced at the plant of the establishment reporting and includes (1) new scrap such as spills, risers, skulls, croppings, mill scale, cinder, etc., and (2) old scrap (any items of equipment discarded after actual use). The term "purchased scrap" includes both purchases and scrap transferred from other plants under the same control as well as scrap received under exchange contracts or conversion agreements. The ratio of total scrap consumption to pig-iron consumption in 1936 was 1:0.82 compared with 1:0.78 in 1935, while the ratio of purchased scrap to pig-iron consumption was 1:1.69 compared with 1:1.58 in 1935 and the ratio of home scrap to pig-iron consumption was 1:1.58 in 1936 compared with 1:1.54 in 1935.

The use of scrap as a raw material in the manufacture of steel increased 38 percent over 1935, and the quantity of pig iron charged directly to steel furnaces increased 46 percent. Likewise, the increase in use of home scrap was greater than that of purchased scrap. The net effect of the relatively greater use of pig iron and home scrap in 1936 was to reduce slightly the proportion of purchased scrap in ferrous materials charged to steel furnaces from 26.4 percent of the total in 1935 to 24.6 percent in 1936.

¹ Where 2 or more separate departments, such as blast-furnace department, open-hearth department, foundry department, etc., are at the same place and are operated by 1 establishment, each of these departments appears as a plant in the total.

² In addition, in 1935, 115,426 tons and in 1936, 105,000 tons were reported consumed in direct castings.

Complete data on the regional consumption of ferrous materials for 1936 are not available at this time, but distribution of quantities used in open-hearth, bessemer, and blast furnaces, which took 78 percent of the total scrap and 86 percent of the pig iron consumed in 1936, are shown below:

In 1935 Ohio led all States in total consumption of scrap, with about 24 percent of the total home scrap, 23 percent of purchased scrap, and 25 percent of the pig iron consumed; Pennsylvania was a close second, with about 24 percent of the home scrap and 19 percent of the purchased, and ranked first in pig-iron consumption, using about 26 percent. Indiana and Illinois followed with about 10 percent each, while Michigan and Wisconsin together took a little less than 10 percent.

¹ Where 2 or more separate departments, such as blast-furnace department, open-hearth department, foundry department, etc., are at the same place and are operated by 1 establishment, each of them appears as a plant in the total.

² In addition, 115,428 tons were reported consumed in direct castings.

For further details on the consumption of iron and steel scrap and pig iron in 1935, the reader is referred to Report of Investigations 3329, Mineral Economic Series, entitled "Consumption of Ferrous Scrap and Pig Iron in 1935", which summarizes the results of the canvass inaugurated in 1935 by the Bureau of Mines in response to requests from industry. The canvass, now being continued on an annual basis, seeks to fill a long existent major gap in data on metal-liferous raw materials.

IRON ORE

Production and shipments.—In 1936, 48,788,745 gross tons of iron ore were produced, an increase of 60 percent over 1935, and the largest output since 1930, but still 25 percent below the 1925–29 average. Of the 196 mines that contributed to the total in 1936, 11 produced more than a million tons each compared with 142 mines (including 5 in the million-ton class) in 1935. Eighteen States were active producers in 1936 compared with 16 in 1935. Shipments of iron ore, which increased 54 percent in 1936 over 1935, totaled 51,465,648 gross tons, the largest amount since 1930 but still 23 percent below the 1925–29 average. The majority of the iron ore mined in the United States is used in the manufacture of iron and steel, but 58,737 tons of ore produced in 1936 were used for other purposes, including the manufacture of cement (42,943 tons), paint (10,348 tons), flux at nonferrous smelters (223 tons), ferromagnesite (4,017 tons), hydrogen gas (461 tons), and gas purification (745 tons).

In the following tables the quantities of iron ore shown include ore that was beneficiated—that is, treated in any way—as well as ore that does not require treatment. Although included in the figures on production, the iron ore sold for the manufacture of paint (10,348

gross tons in 1936 valued at \$53,037 (\$5.13 a ton) compared with 4,795 tons in 1935 valued at \$28,683 (\$5.98 a ton)) is not included in the shipments from mines. The output of manganiferous ore that contained 5 percent or more manganese is also not included; 940,519 tons valued at \$2,235,366 were shipped in 1936 compared with 524,184 tons valued at \$1,322,611 in 1935. In Arkansas, one producer shipped 5 gross tons of loadstone, which is not included in the iron-ore statistics. Neither do the statistics include iron sinter recovered from the roasting of pyrites concentrate in Tennessee.

Principal iron-ore mines.—The importance of large mining units in the iron-mining industry is shown by the fact that in 1936 44 mines yielding more than 300,000 tons each produced nearly 80 percent of the entire output. Eleven mines—nine in Minnesota, one in Pennsylvania, and one in Alabama—produced more than a million tons each. Of the 44 principal producing mines, 18 were open pits, 21 were operated by underground methods alone, and 5 were combination. Hematite was produced by 42 of the 44 principal mines; the other 2 produced magnetite.

Iron-ore mines of the United States (arranged in order of rank) that produced more than 300,000 gross tons each in 1936

[All mines produced hematite except Cornwall and Witherbee Sherman group, which produced magnetite]

Grand total of United States (196 mines).....					48, 788, 745

Beneficiated iron ore.—Beneficiation of iron ore was reported at 45 mines in 6 States in 1936 and at 39 mines in 6 States in 1935. At many mines the ore is crushed and screened to improve its structure; ore so improved, however, is not included in the statistics of beneficiated ore. Some iron ore is recovered in the form of dust from blast furnaces; ore so recovered, however, has been included originally in the statistics of shipments from mines.

Beneficiated ore shipped from domestic mines comprised 19 percent of total shipments and amounted to 9,658,699 gross tons valued at \$25,937,597 in 1936, compared with 6,066,601 tons valued at \$15,174,259 in 1935.

The concentratability of the important iron ores of the United States has been discussed by Cooke.²

² This figure includes value for States entered as (1) above.

³ Cooke, S. R. B., *Microscopic Structure and Concentratability of the Important Iron Ores of the United States*: Bull. 391, Bureau of Mines, 1936, pp. 1-121.

The quantity of crude ore beneficiated in the Lake Superior district in 1936 totaled 11,101,716 gross tons and the beneficiated ore recovered 6,822,278 tons—a ratio of 1.627 to 1. In 1935 the crude ore treated totaled 8,567,752 tons and the beneficiated ore recovered therefrom 4,884,192 tons—a ratio of 1.754 to 1. Most of the concentration in this district is done by washing, but a few plants are equipped with jigs. In recent years there has been developed on the Mesabi range a process for roasting ore to the magnetic state and concentrating on magnetic separators. The process, which is applicable to ores that cannot be concentrated either by washing or jigging, has been described by Davis.³

The following table shows that beneficiated ore is becoming a larger part of the total. Corresponding statistics for 1914 (the first year for which they were gathered) to 1927 are given in Mineral Resources for 1930. The figure for 1932 shows that in years of very low demand the richer ores are selected for mining and shipment.

Iron ore shipped from mines in the United States, 1927-31 (average) and 1932-36, in gross tons, and percentage of beneficiated ore compared to the total shipped

[Exclusive of ore containing 5 percent or more manganese and of ore sold for paint]

¹ Average.

Average value of ore.—The average value per gross ton of iron ore at the mines was \$2.56 in 1936 compared with \$2.48 in 1935.

The table that follows gives the average value at the mines of the different classes of iron ore in 1935-36 for each of the producing States or groups of States, except where there are less than three shippers of a certain variety of ore in a State and permission was not given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately, as not all reports are comparable. Some evidently include mining costs only; others contain, in addition, the cost of selling and insuring the ore; others include an allowance for sinking fund; and still others comprise only costs charged against blast furnaces. None of the reports, however, is supposed to include freight charges.

³ Davis, E. W., *First Magnetic Roasting Plant in the Lake Superior Region*: Am. Inst. Min. and Met. Eng. Tech. Pub. 731, 1937, pp. 1-19.

Iron ore consumed.—The production of 30,254,022 gross tons of pig iron in 1936 required 51,835,257 tons of iron and manganiferous iron ores, 3,521,544 tons of mill cinder and roll scale, and 903,310 tons of purchased scrap, an average of 1.860 tons of metalliferous materials per ton of iron made. In addition, 1,183,000 tons of home scrap and 1,340,600 tons of flue dust were consumed in 1936.

The greater part of the iron ore used in Alabama furnaces in 1936 was hematite, chiefly from mines in Jefferson County, but some came from Etowah and St. Clair Counties. Considerable brown ore, iron sinter, imported iron ore and manganese ores, and small quantities of ferruginous manganese and manganiferous iron ores were used. The brown ore was chiefly from mines in the Birmingham and Russellville districts, Alabama; the iron sinter was from Tennessee; and the ferruginous manganese ores and manganiferous iron ores came from Alabama, Arkansas, Georgia, and Tennessee. Imported manganese-bearing ores came from Cuba. In 1936 Alabama furnaces consumed an average of 2.312 tons of ore in making 1 ton of pig iron, the highest average for any State.

During 1936, in addition to foreign ores from Australia, Cuba, U. S. S. R. (Russia), and Chile, Maryland furnaces consumed considerable domestic ore. These furnaces used an average of 1.513 tons of ore in making 1 ton of pig iron; however, they used proportionately more cinder, scale, and scrap than furnaces in any other State except Kentucky.

The blast furnaces in Illinois, Indiana, Kentucky, Michigan, Minnesota, Ohio, and West Virginia operated on Lake Superior iron ore and manganiferous iron ore exclusively.

In New York the furnaces in the Buffalo district employed ore chiefly from the Lake Superior district, the furnace at Standish magnetite from the Chateaugay mine at Lyon Mountain, N. Y., and the furnace at Troy chiefly magnetite from Mineville, N. Y.

Virtually all of the ore consumed in furnaces in western Pennsylvania came from the Lake Superior district. Those in the eastern part of the State used some lake ores; magnetite ores from Pennsylvania, New Jersey, and New York; and considerable quantities of ore from Africa, Asia, Australia, Brazil, Chile, Cuba, and Sweden.

The blast furnaces at Pueblo, Colo., employed hematite from the Sunrise mine in Wyoming, magnetite from New Mexico, rhodochrosite from Butte, Mont., and manganese-bearing ores from Colorado, New Mexico, and Utah.

The Provo (Utah) furnace consumed hematite from the Desert Mound mine near Iron Springs, Utah, semialtered magnetite from the Iron Mountain mine near Cedar City, and manganese tailings from Philipsburg, Mont.

The furnace in Tennessee used brown ore and iron sinter from Tennessee.

Iron ore and other metallic materials consumed and pig iron produced in 1936, by States, in gross tons

¹ 1936; Algeria only.

Exports of iron ore from the United States totaled 645,284 gross tons valued at \$1,962,527 (\$3.04 a ton) in 1936, compared with 660,553 tons valued at \$1,913,463 (\$2.90 a ton) in 1935. Of the 1936 total, 636,524 tons valued at \$1,911,866 went to Canada, 5,602 valued at \$16,104 went to the United Kingdom, 3,063 valued at \$33,085 went to Japan, and 95 tons valued at \$1,472 went to Mexico.

Iron-ore mining in Cuba.—Shipments of iron ore from Cuba to the United States doubled in 1936 over 1935. The 1936 total of 449,611 gross tons included 254,354 tons of hematite carrying (dried) 56.69 percent iron and 124,215 tons of siliceous ore carrying (dried) 32.06 percent iron from the Daiquiri-Juragua mines on the southern coast, and 71,042 tons of nodulized brown ore carrying (dried) 54.92 percent iron from the Mayari mines near the northern coast.

The total stock of ore reported on hand was 386,828 gross tons at the end of the year compared with 571,987 tons at the end of 1935.

The following table shows the shipments of iron ore from Cuba since the mines were opened in 1884. The statistics of shipments of Cuban iron ore are collected by the Bureau of Mines.

Iron ore shipped from mines in the Province of Oriente, Cuba, 1884-1936, in gross tons

Year	Juragua (hematite and mag- netite), Daiquiri (hematite and a little magnetite)	Sigua (hematite)	Mayari (brown ore)	Guamá (hematite)	El Cuero (hematite)	Total
1884-1934.....	20,775,919	20,438	3,693,326	41,241	903,103	25,434,027

¹ Of this quantity, 5,932 tons were sent to Pictou, Nova Scotia, and 64,228 tons to ports outside of the United States.

REVIEW OF LAKE SUPERIOR DISTRICT

Production.—The total quantity of iron ore mined in the Lake Superior district (the principal producing district) was 41,780,889 tons in 1936, an increase of 65 percent over 1935. Output from this district, which produced 86 percent of the domestic total in 1936, comes from several ranges; of these the Mesabi is the largest producer, contributing 72 percent of the district total and 62 percent of the United States total in 1936. The output, by ranges, is shown in the following table. After 1905, the figures do not include manganiferous iron ore containing 5 percent or more manganese.

Iron ore mined in the Lake Superior district, 1854–1936, by ranges, in gross tons

[Exclusive after 1905 of ore containing 5 percent or more manganese]

Year	Marquette	Menominee	Gogebic	Vermillion	Mesabi	Cuyuna	Total
1854–1934	182,020,768	176,890,254	194,795,363	61,391,930	935,663,924	23,955,657	1,574,726,896
1935	2,865,292	730,456	2,397,994	846,617	18,323,695	204,311	25,368,365
1936	4,423,420	1,642,548	4,080,857	1,049,722	30,205,378	378,964	41,780,889
	189,309,480	179,272,258	201,274,214	63,288,269	984,192,997	24,538,932	1,641,876,150

Shipments.—The shipments of ore from the Lake Superior district amounted to 45,250,767 gross tons (44,352,214 tons of iron ore and 898,553 tons of manganese-bearing ores containing 5 percent or more of manganese) in 1936 compared with 28,504,821 tons (27,995,498 tons of iron ore and 509,323 tons of manganese-bearing ores) in 1935. The iron-ore statistics given above include 3,126 tons of paint ore in 1936 and 1,923 tons of paint ore in 1935.

Iron-ore analyses.—The iron content of the iron ore and manganiferous iron ore shipped from the Lake Superior district in 1936 averaged 51.45 percent (natural) compared with 51.44 percent in 1935 and 51.49 percent in 1934.

The following table, compiled by the Lake Superior Iron Ore Association, summarizes the average analyses of the total tonnages of all grades of ore shipped and shows the remarkable uniformity maintained during the past 5 years. This uniformity does not mean, of course, that the average grade of the available Lake Superior ore is not declining. The grade of shipments has been maintained partly by beneficiation and partly by mixing ores from different deposits.

Average analyses of total tonnages of all grades of iron ore from all ranges of Lake Superior district, 1932–36

Year	Gross tons	Iron (natural)	Phosphorus	Silica	Manganese	Moisture
		Percent	Percent	Percent	Percent	Percent
1932	3,552,575	52.16	0.099	8.05	0.68	9.92
1933	21,455,174	51.85	.090	8.96	.71	10.47
1934	21,841,382	51.49	.087	8.93	.76	10.66
1935	28,214,056	51.44	.093	8.93	.79	10.75
1936	44,745,754	51.45	.091	8.62	.81	10.92

Stocks of ore at Lake Erie ports.—At the close of navigation in 1936, according to the Lake Superior Iron Ore Association, 4,918,348 gross tons were in stock at Lake Erie ports compared with 5,313,265 tons

on the corresponding date in 1935. At the opening of navigation in May 1937, only 2,336,653 tons were in stock at these ports (the lowest since 1907), indicating a withdrawal of 2,581,695 tons during the winter 1936-37.

Prices of Lake Superior ore.—The unit prices established April 1, 1936, for the four standard grades of Lake Superior ore are the same as those for 1929-35, as follows: Old-range Bessemer, 9.32 cents; Mesabi Bessemer, 9.029 cents; Old-range non-Bessemer, 9.029 cents; and Mesabi non-Bessemer, 8.738 cents. The prices per gross ton that correspond to these prices are, respectively, \$4.80, \$4.65, \$4.65, and \$4.50. The base of Bessemer ore, Old-range and Mesabi, for 1925-36 is a metallic content of 51.5 percent (natural) instead of 55 percent, as for 1924 and many earlier years. The base of the non-Bessemer ore, Old-range and Mesabi remains as heretofore at 51.5 percent (natural).

Iron-ore reserves.—Estimates of ore reserves for Minnesota, furnished by the Minnesota Tax Commission, and for Michigan, furnished by the Michigan Board of Tax Commissioners, shown in the following tables, cover developed and prospective ore in the ground and ore in stock piles. These estimates exhibit an increase over the previous year of 1,147,424 tons in Minnesota and a decrease of 4,391,304 tons in Michigan. Reserves in Wisconsin have been estimated at 6,000,000 tons.

IRON ORE MINING BY STATES

Alabama.—In 1936, 4,179,967 gross tons of iron ore (3,739,221 tons of hematite and 440,746 tons of brown ore) were produced in Alabama, an increase of 28 percent over 1935. About 89 percent of the Alabama output in 1936 came from underground operations. The hematite, much of which contains enough lime to make it self-fluxing or nearly so, was produced chiefly at the Raimund Nos. 1 and 2, Red Mountain group, Sloss Nos. 1 and 2, and Woodward No. 3 mines, all underground operations in Jefferson County. Five (four open pit and one underground) other smaller operations in Etowah and St. Clair Counties contributed to the total for hematite ore. The iron content of the hematite produced in 1936 averaged (natural) 35.98 percent, the manganese content 0.16 percent, the phosphorus content 0.31 percent, and the lime content 16.35 percent. The Red Mountain group (1,897,103 tons) was the largest producing iron mine in Alabama and the fourth largest in the United States in 1936.

The brown ore mined in 1936, which averaged 48 percent iron (natural) and 0.66 percent manganese, was produced by a number of mines but chiefly from the Russellville mines in Franklin County, the Champion mines in Blount County, and the Reno mine in Tuscaloosa County.

California.—Production in California in 1936 of 31,395 gross tons came from three mines, two in San Bernardino County and one in Placer County. Virtually all of the San Bernardino ore, which was hematite containing (natural) 58.75 percent iron, was used in cement manufacture and the Placer County ore (brown ore) absorbed by the paint industry.

Georgia.—Production in Georgia in 1936, amounting to 5,740 gross tons, came from 10 operations, 6 in Bartow County and 4 in Polk County. The output, all brown ore, contained 28 to 51 percent iron and 0.3 to 5.0 percent manganese.

Michigan.—Output in Michigan increased 76 percent in 1936 over 1935 and totaled 9,177,629 gross tons. Eighty-two percent of the total came from underground mines in 1936; but the largest producer, the Plymouth mine, was an open-pit operation. The iron content (natural) of the ore mined in 1936 averaged 51.83 percent compared with 51.81 percent in 1935.

Increased production on the Michigan ranges in 1936 resulted in increased employment, and a scarcity of skilled underground miners necessitated the training of younger men.

Reserves in Michigan amounted to 154,032,944 gross tons at the end of 1936, a decrease of 4,391,304 tons from the previous year.

A report on the iron-ore mines of Michigan for 1936, published by the geological survey division of the Michigan Department of Conservation,⁴ shows that the average number of men employed was 4,929 (4,172 in 1935), the average number of days worked 238 (196 in 1935), the average daily wage \$4.87 (\$4.62 in 1935), the average yearly earning \$1,160.18 (\$905.95 in 1935), and the average tons of ore mined per man per day 5.58 (5.40 in 1935).

The data in the following table on average per-ton costs of mining ore at underground mines and at siliceous open pits have been abstracted from statistics published in much greater detail by the Geological Survey Division of Michigan.

Average per-ton costs of mining iron ore at underground mines and at siliceous open pits in Michigan in 1936

¹ This figure does not represent true profit, as much ore is sold below the Lake Erie price.

⁴ Pardee, F. G., and Eddy, G. E., General Statistics Covering Costs and Production of Michigan Iron Mines: Michigan Dept. of Conservation, Geol. Survey Div., Lansing, 1937.

Minnesota.—In 1936 production of iron ore in Minnesota, the principal producing State, increased 63 percent over 1935, to 31,634,064 gross tons, and was the largest since 1930. Output from open-pit mines increased 74 percent and thus supplied 86 percent of the Minnesota total compared with 81 percent in 1935. From this it appears that under pressure for increased production open pits respond more quickly than underground operations. Of the 11 mines producing more than 1 million tons each in 1936, 9 were in Minnesota; of these, 7 were open pits and 2 employed combination open-pit and underground operations. Of the 68 active mines in Minnesota in 1936 (56 in 1935), 46 (36 in 1935) yielded more than 100,000 tons each. The iron content (natural) of the ore mined in 1936 averaged 51.64 percent compared with 52.11 percent in 1935.

According to the annual report of the mine inspector of St. Louis County, an average of 4,694 men was employed in iron mines in St. Louis County during 1936 (4,079 in 1935), and the average daily wage was \$5.32 (\$5.20 in 1935) for 8 hours. In 1936, 1,683,664 cubic yards of overburden were removed compared with 1,586,978 cubic yards in 1935.

In Crow Wing County (Cuyuna range), according to the mine inspector's report, 563 men were employed in 1936 compared with 305 men in 1935. In 1936, 870,303 cubic yards of overburden were removed, compared with 539,628 yards in 1935.

Missouri.—Three mines produced 3,272 gross tons of iron ore in Missouri in 1936 compared with three mines and 2,544 tons in 1935. The ore, all hematite, was used by the iron and steel and paint industries.

New Jersey.—Output of iron ore in New Jersey more than doubled in 1936 over 1935 and totaled 159,906 gross tons. The ore, all magnetite and all produced from underground operations, came from two mines, the Scrub Oaks and the Richards, both near Dover, N. J. New Jersey ores are crushed and concentrated magnetically before shipment. Concentrates from the Scrub Oaks mine averaged (dried) 67.27 percent iron and 0.035 percent phosphorus, and the ore from the Richards mine contained (dried) 60.29 percent iron. The present status of iron mining in New Jersey has been described recently by Roche.⁵

New Mexico.—One operation in New Mexico produced 17,621 gross tons of magnetite carrying (natural) 58 percent iron in 1936.

New York.—The production of iron ore in New York, which increased 162 percent over 1935 and amounted to 777,643 gross tons, was chiefly magnetite from underground operations at the Harmony and Old Bed shafts in Essex County and the Chateaugay mine in Clinton County. Some hematite was mined for paint in Oneida and Wayne Counties. Shipments from New York in 1936 included 627,056 tons of sinter averaging 67.89 percent iron, 125,029 tons of lump ore averaging 61.52 percent iron, and 49,151 tons of concentrates averaging 68.50 percent iron.

North Carolina.—The Maltby mine in Cherokee County produced and shipped 57 tons of brown ore, the total for North Carolina in 1936.

Pennsylvania.—Pennsylvania, the most important source of magnetite in the United States, produced 1,132,215 gross tons of ore in 1936 compared with 979,638 tons in 1935. The production consisted chiefly

⁵ Roche, H. M., *The Iron Ores of New Jersey: Iron Age*, vol. 139, no. 5, Feb. 4, pp. 74-80, and no. 7, Feb. 18, 1937, pp. 39-43.

of 1,131,682 tons of magnetite from the Cornwall mines in Lebanon County; it averaged 42.74 percent iron (natural). Some carbonate ore for use in paint was mined in Carbon County in 1936.

Tennessee.—The output and shipments from Tennessee in 1936, amounting to 27,617 gross tons of brown ore, came from two open-pit operations. The Van Leer mine in Lawrence County produced 5,456 tons of brown ore concentrates averaging (natural) 42 percent iron, and the Johnson mine in Hickman County produced 22,161 tons containing 48 percent iron (natural).

A considerable quantity of iron sinter is made annually from roasted pyrites concentrates in Ducktown Basin in Polk County, but this material is not included in the statistics of iron ore. In 1936 this sinter contained 66.44 percent iron and 0.006 percent phosphorus.

Utah.—The production of iron ore in Utah in 1936, which decreased 4 percent from 1935, amounted to 154,191 gross tons; of this, 39,489 tons were hematite and most of the remainder magnetite. The largest output came from the Iron Mountain mine in the Iron Springs district, a new mine opened in 1936. The ore, which is semialtered magnetite, contains (natural) 57.33 percent iron. A small part of the shipments from this mine went for flux at nonferrous smelters and for cement manufacture. The Desert Mound mine, also in the Iron Springs district, produced and shipped all the hematite in Utah in 1936; the ore averaged (natural) 52.3 percent iron. Some brown ore (268 tons) was shipped from the Tecoma mine in Box Elder County in 1936 for use in paint.

The following is an abstract of a paper prepared in 1936 by F. G. Wells of the United States Geological Survey on the origin of the iron ore in the Bull Valley and Iron Springs districts of Utah.

The iron-ore deposits of the Bull Valley and Iron Springs districts, Utah, consist of veins of magnetite and hematite in monzonite, and magnetite-hematite replacement bodies in limestone. Neither ores nor country rock show features characteristic of contact metamorphic deposits. The following explanation of the origin of the deposits is offered. During the intrusion of monzonite porphyry stocks, the hoods and overlying rock were fractured, causing a sudden release of pressure and liberating FeCl_2 and H_2O gas from the stocks, which were still at high temperature. These gases found ready egress to the surface along tension fissures without appreciably heating the country rock. They deposited magnetite and hematite in the fissures and replaced the contiguous fractured limestone. The period of gas emanation was brief, and the hydrothermal phase probably evolved during the later magmatic history never reached this area. The deposits were formed under a cover of less than 5,000 feet.

Virginia.—The production of iron ore in Virginia in 1936 amounted to 745 gross tons of hematite, containing (natural) 56.06 percent iron and 0.06 percent phosphorus, from the Chestnut Flat mine in Giles County, and 461 tons of brown ore, containing 45 percent iron, from the Oriskany mine in Botetourt County. The hematite was shipped for gas purification and the brown ore for use in hydrogen gas manufacture.

Washington.—Three mines, two yielding hematite and the other magnetite, produced 9,082 gross tons of iron ore in Washington in 1936. All of the magnetite came from the Big Iron mine in Stevens County; it contained 60.10 percent iron (natural) and was used in making ferromagnesite. The ore from Keystone mine in Washington County, containing 56.65 percent iron (natural), was used for cement. The other hematite ore, which contained (natural) 25.27 percent iron and 48.32 percent silica, was also used for cement.

Wisconsin.—The Montreal mine, an underground operation in Iron County, was the largest producer of iron ore in Wisconsin, contributing 802,536 gross tons of the 969,522 produced in Wisconsin in 1936. The ore, which is hematite, averaged (natural) 53.06 percent iron, 1.50 percent manganese, and 0.054 percent phosphorus. The Cary mine, also an underground operation in Iron County, was the other chief producer in 1936, furnishing 166,660 tons of hematite containing (natural) 55.39 percent iron, 0.39 percent manganese, and 0.046 percent phosphorus. In addition, 326 tons of hematite were produced and shipped for paint from the Iron Ridge mine in Dodge County. Shipments from Wisconsin mines totaled 918,935 tons in 1936.

Wyoming.—Output of iron ore from Wyoming in 1936 came from the Sunrise mine and comprised 507,278 gross tons of hematite containing (dried) 56.3 percent iron, 0.09 percent manganese, 0.064 percent phosphorus, and 11.1 percent silica. Production came from open-pit and underground operations.

MEN EMPLOYED AND OUTPUT PER MAN AT IRON-ORE MINES

Accelerated activity at blast furnaces and steel plants in 1936, which increased the demand for iron ores, undoubtedly increased employment at iron mines, also. Statistics of employment in 1936 are not available as yet, but some of the districts reported a shortage of experienced underground miners due to curtailment of operations during the depression, when the men either left the area or found employment in other industries and were reluctant to return to mining. To remedy this condition some of the companies placed younger men with capable miners, thereby training new help and continuing production under safe conditions. Wage increases were common during 1936, and in many districts vacations with pay were inaugurated. The extent of the vacation was based, in part, on the length of service.

During 1935, the last year for which statistics are available, greater demand for iron ore resulted in increasing labor at iron mines, but the

FIGURE 33.—Trends in number of men employed at iron-ore mines, output of merchantable ore, man-hours worked, and output per man-hour in the United States, 1923-35.

increase in man-hours did not parallel the increase in output, and the average number of men employed declined. In 1935, 14,987 men, working 26,281,693 man-hours, produced 30,540,252 gross tons of merchantable ore, an average output of 1.162 tons per man-hour; while in 1934, 16,513 men, working 25,478,440 man-hours, produced 24,587,616 tons of ore, or 0.965 ton per man-hour. Thus, from 1934 to 1935 the total man-hours worked increased 3 percent, while the total merchantable ore increased 24 percent and the average output per man-hour increased 20 percent. The output per man-hour in 1935 exceeded that for any year since records have been compiled and undoubtedly was greater than in any other year. This relatively small labor requirement in 1935 was the result of several factors, including increased output from open-pit mines, decrease in stripping per ton of open-pit ore, nearer capacity production of operating units, and increase in number of days worked per year. Conversely, the relative amount of beneficiated ore increased in 1935 to nearly 19.9 percent of the total output, but apparently this was overshadowed by the items listed above.

The number of man-hours of labor increased in 1935 over 1934 in all districts except the Lake Superior region, the principal producing area. In this district the output of merchantable ore per man-hour increased 22.5 percent, from 1.100 tons in 1934 to 1.348 tons in 1935. With an increase in production of 4,337,618 tons (21 percent), the average number of men employed, the total man-shifts, and the total man-hours declined. The average number of days worked increased, however. A large part of the output of this district comes from Minnesota, where open pits furnished 81 percent of the ore in 1935. Output per man-hour in Minnesota increased 31 percent, from 1.428 tons in 1934 to 1.877 tons in 1935. Although, as was pointed out in Minerals Yearbook, 1934 (p. 322), the improved performance in mining iron ore has been closely related to advances in mechanization, improved mining methods, operation of larger units, and more efficient management of mines, the gain in 1933, 1934, and 1935 compared with the 10 years 1923-32 was due chiefly to the expansion of open-pit operations in Minnesota. For example, while about 75 percent of the merchantable ore produced in Minnesota from 1923 to 1932 came from open-pit mines, 82 percent was so produced in 1933-35. The significance of this shift can be appreciated when it is recalled that Minnesota contributed more than 60 percent of the total merchantable ore produced during the period 1923-35, and that during that period the output of men at open-pit operations averaged 1.848 tons per man-hour compared with only 0.684 ton per man-hour for workers at underground mines.

The greater output per man-hour in recent years was also due in part to the stripping of proportionately less overburden in Minnesota in 1933, 1934, and 1935 in preparation for future mining than in the period 1923-32. In 1933-35, about one-fourth cubic yard of overburden was removed for each ton of merchantable ore mined in Itasca and St. Louis Counties, Minn., whereas during the 10 years 1923-32 about one-half cubic yard of overburden was removed for each ton of merchantable ore mined. Any material shift in the labor force to the direct mining of ore at the expense of that used for stripping will result in a much lower man-hour cost of mining for any year. This is strikingly illustrated in figure 34, which shows that in 1926, 1933, 1934, and 1935, when only about one-fourth cubic yard of overburden was removed to each ton of merchantable ore mined at both open-pit and underground mines, the average output per worker increased substantially, whereas during the other years, when one-third to four-fifths cubic yard of overburden was removed to each ton of ore mined, the output of the worker decreased.

Another factor that affects the output per man-hour is the tendency to mine leaner ore. Proportionately more lean ore requiring beneficiation has been mined in Minnesota in recent years than during 1923-32. In 1935, for instance, beneficiated ore represented 25 percent of the total merchantable ore produced in Minnesota compared with an average of 20.72 percent for 1933-34 and with an average of only 16.07 percent during the period 1923-32.

The bulk of the ore in the Southeastern district, the second largest producing region, is obtained from underground operations. Output of merchantable ore per man-hour in this area increased from 0.503 ton per man-hour in 1934 to 0.588 ton per man-hour in 1935. The largest and most consistent producing mines in the Southeastern district are in Jefferson County, Ala., where 2,532 men working 4,449,974

man-hours in 1935 produced 3,009,740 tons of merchantable ore, equivalent to an average output per man-hour of 0.676 ton; 2,444 men working 3,726,143 man-hours in 1934 produced 2,049,915 tons of merchantable ore, equivalent to an average output per man-hour of 0.550 ton. All ore produced in Jefferson County comes from underground operations. In comparing the man-hour cost of mining ore in Jefferson County, Ala., with that at underground mines in the Lake

FIGURE 34.—Trends in output of merchantable iron ore per man-hour at open-pit and underground mines in Minnesota compared with production of merchantable and lean ore, and total man-hours worked, 1923-35.

FIGURE 35.—Trends in production, man-hours worked, output per man-hour, and number of men employed at iron-ore mines in Jefferson County, Ala., 1923-35.

Superior district, one should remember that whereas the ore in the Lake Superior district is considerably richer in iron, the ore from the Jefferson County mines contains enough or almost enough lime to make it self-fluxing. Thus, it should be recognized that the lower iron content is partly offset by the self-fluxing nature of the ore, although it is impossible to show this important characteristic in the productivity figures.

In the Northeastern district the average output of merchantable ore per man-hour increased from 0.639 ton in 1934 to 0.917 ton in 1935. The rise in productivity was due chiefly to the large increase in output of the Cornwall open pit at Miners Village, Pa., where a relatively high output per man-hour is attainable. Most of the other production in this area comes from underground mines, and the greater part of the ore is subjected to concentration.

The average length of the man-shift in the entire iron-ore industry in 1935 was 8 hours, the same as in 1934. With few exceptions, mines employed the 8-hour shift throughout 1935.

The two following tables, prepared in collaboration with W. W. Adams, show employment at iron-ore mines and beneficiating plants, quantity and tenor of ore produced, and the average output per man by districts for 1923-35 and by States for 1934-35. Corresponding statistics by States for 1923-32, as well as other supplementary data, are given in the chapter on Iron Ore, Pig Iron, Ferro-Alloys, and Steel in *Minerals Yearbook, 1934* (pp. 322-339).

WORLD PRODUCTION

The following table shows the production of iron ore by countries from 1932 to 1936 so far as statistics are available. Complete returns for 1936 are not yet available, but those for 1935 are nearly complete. Thus, the data for 1935 indicate a production of 141,000,000 metric tons; the United States furnished about 22 percent.

Iron ore produced, 1932-36, by countries, in metric tons

PIG IRON

Production and shipments.—Domestic production of pig iron, exclusive of ferro-alloys, increased 45 percent in 1936 over 1935. The output in 1936 comprised 30,176,971 gross tons using coke as fuel and 77,051 tons made with charcoal. Pennsylvania, second to Ohio in 1935, regained first place in 1936. Of the pig iron manufactured in 1936, it is calculated that 1,131,970 tons, valued at \$21,857,096, were made from 1,875,723 tons of foreign ores from Africa, Asia, Australia, Brazil, Chile, Cuba, India, Newfoundland, Sweden, and the U. S. S. R. (Russia), indicating an average yield of 60.35 percent from imported ore. Domestic ore (49,959,534 tons) and 4,424,854 tons of cinder, scale, and purchased scrap, amounting in all to 54,384,388 tons, were reported used in the manufacture of 29,122,052 tons of pig iron, indicating an average pig-iron yield from domestic materials of 53.55 percent. In addition, 1,183,000 tons of home scrap and 1,340,600 tons of flue dust were consumed in making pig iron in 1936.

Shipments of pig iron, exclusive of ferro-alloys, were 30,798,958 gross tons, valued at \$541,693,504 in 1936, an increase over 1935 of 45 percent in quantity and 51 percent in total value. Shipments of pig iron were still 19 percent below the 1925-29 average. The values given represent the approximate amounts received for the iron, f. o. b. furnaces, and do not include freight costs, selling commissions, and other items that are figured in some of the market prices of pig iron published in trade journals.

¹ American Iron and Steel Institute.

Value at blast furnaces.—The average value of all kinds of pig iron given in the accompanying table is based on the reports of the manufacturers to the Bureau of Mines. The figures represent the approximate values, f. o. b. blast furnaces, and do not include the values of ferro-alloys. The general average value for all grades of pig iron at the furnaces was \$17.59 a gross ton in 1936—\$0.68 more than in 1935 but \$1.01 less than the 1925-29 average.

World production of pig iron.—World production of pig iron (including ferro-alloys) in 1936 was approximately 93,000,000 metric tons, an increase of 23 percent over 1935 and 8 percent above the 1925-29 average. In 1936 the United States supplied 34 percent of the world output of pig iron compared with 29 percent in 1935, in consequence of a 45-percent increase in United States production in 1936 over 1935 compared with a 14-percent increase for the rest of the world.

¹ In addition to countries listed, pig iron is produced in Chile, but production figures are not available.

² Approximate production.

FERRO-ALLOYS

Production and shipments.—The production of ferro-alloys was 818,488 gross tons in 1936, compared with 545,316 tons in 1935, an increase of 50 percent. Ferro-alloys were made in 1936 at 12 blast furnaces, 15 electric furnace plants, and 2 aluminothermic plants; in addition, 2 plants made ferrophosphorus and 1 plant made ferrosilicon as a byproduct.

The shipments of all classes of ferro-alloys totaled 853,531 gross tons valued at \$69,135,074 in 1936, an increase of 44 percent in quantity and 41 percent in total value over 1935. Compared with the 5-year average for 1925–29, which amounted to 715,250 tons, the 1936 shipments increased 19 percent.

Ferro-alloys shipped from furnaces in the United States, 1935–36, by varieties

* 1935: Ferrochromium, ferromolybdenum and calcium-molybdenum compounds, ferrophosphorus, ferrotitanium, ferrozirconium, silicomanganese, silicospiegeleisen, ferrocolumbium, and zirconiumferrosilicon; 1936: Ferrochromium, ferromolybdenum and calcium-molybdenum compounds, ferrotitanium, ferrovanadium, ferrozirconium, silicomanganese, silicospiegeleisen, ferrocolumbium, and zirconiumferrosilicon.

Ferromanganese.—The shipments of ferromanganese in 1936 increased 66 percent over those of 1935 and totaled 322,353 gross tons. Compared with the 5-year average for 1925–29 (303,883 tons) the 1936 shipments increased 6 percent. The average value per ton, f. o. b. furnaces, reported for ferromanganese was \$74.73 in 1936, compared with \$84.13 in 1935.

The production of ferromanganese in 1936, amounting to 316,000 gross tons containing 249,933 tons of manganese (79.09 percent manganese), was made at six blast furnaces and two electric furnace plants. In 1935, the production, which was 214,290 tons containing 170,168 tons of manganese (79.41 percent manganese), was made at five blast furnaces and two electric furnace plants. In both years the bulk of the output was made in blast furnaces.

Ferromanganese produced in the United States and metalliferous materials consumed in its manufacture, 1932–36

Year	Ferromanganese produced			Materials consumed (gross tons)				Manganese ore used per ton of ferromanganese made (gross tons)
	Gross tons	Manganese contained		Manganese ore		Iron and manganese ferrous iron ores	Cinder, scale, and purchased scrap	
		Percent	Gross tons	Foreign	Domestic

The tons of manganese ore used per ton of ferromanganese produced increased from 1.793 in 1933 to 1.902 in 1936. Of the total manganese ore used in making ferromanganese in 1936, only 1 percent was mined in the United States; 99 percent came from foreign sources, as shown in the following table.

Quantity and tenor of manganese ore used in manufacture of ferromanganese in the United States, 1935-36

Spiegeleisen.—Shipments of spiegeleisen from domestic furnaces in 1936 increased 69 percent over 1935 and totaled 92,336 gross tons. Shipments, however, were still 8 percent below the 1925-29 average—99,964 tons. The average value per ton at the furnace was \$24.36 in 1936 and \$23.79 per ton in 1935. Production in 1936 was 95,137 tons, the bulk of which was made in blast furnaces; only a small amount came from electric furnaces. Output in 1936 averaged 20.57 percent manganese. Most of the spiegeleisen was made from domestic ores in 1936, but 31,159 tons of foreign ferruginous manganese ore also were used.

Ferrosilicon.—Shipments of ferrosilicon in 1936 increased 24 percent over 1935 and amounted to 325,210 gross tons. Compared with the 5-year average for 1925-29 (261,688 tons), the 1936 shipments increased 24 percent.

The production of ferrosilicon in 1936 was 294,441 gross tons, including 164,699 tons made by blast furnaces, 129,454 tons by electric furnaces, and 288 tons as a byproduct of the manufacture of artificial abrasives in electric furnaces. The silicon content of the production in 1936 ranged from 7 to 95 percent, but averaged 22.28 percent. Virtually all the raw material used in making ferrosilicon was of domestic origin.

Ferrophosphorus.—Shipments of ferrophosphorus in 1936 totaled 19,341 gross tons valued at \$1,279,143. Production was 20,771 gross tons containing 21.54 percent phosphorus. Most of the output was made in blast furnaces. Ferrophosphorus was made entirely from domestic materials in 1936.

Ferrotungsten.—Shipments of ferrotungsten increased 21 percent in 1936 over those of 1935 and amounted to 1,812 gross tons containing about 80 percent tungsten (3,250,621 pounds). The value of the 1936 shipments was \$3,912,037, f. o. b. furnaces, or \$1.20 per pound of contained tungsten. The 1936 shipments were only 3 percent below the average of 1,864 tons for the 5-year period 1925-29.

The production of ferrotungsten in 1936 was 1,865 gross tons containing 80 percent tungsten (3,341,525 pounds). In addition to domestic ores from Arizona, California, Colorado, Nevada, and Washington, foreign ores from Australia, China, India, and South America were used. All ferrotungsten was made in electric furnaces.

Foreign trade in ferro-alloys.—Imports of all alloys of the rarer metals are not recorded separately but are grouped as shown in the following table. Ferromanganese and spiegeleisen constituted the bulk of the imports in 1935 and 1936. The imports of ferromanganese for consumption (chiefly from Norway and Netherlands) were 37,953 gross tons, an increase of 39 percent over 1935. The imports of spiegeleisen for consumption (chiefly from Canada) were 52,011 gross tons; an increase of 61 percent.

STEEL

Production.—The following figures covering the output of steel were compiled by the American Iron and Steel Institute. The total production of steel ingots and castings in 1936 amounted to 47,767,856 gross tons, an increase of 40 percent over 1935 and within 3 percent of the 1925-29 average of 49,320,025 tons. Of the total steel output in 1936, 43,536,128 tons (91 percent) came from open hearths, 3,458,457 tons (7 percent) from bessemer converters, 772,455 tons (1.6 percent) from electric furnaces, and 816 tons from crucible furnaces. In 1935 the production was 34,092,594 tons, of which 30,715,429 tons (90 percent) came from open hearths, 2,835,031 tons (8 percent) from bessemer converters, 541,492 tons (1.6 percent) from electric furnaces, and 642 tons from crucible furnaces. Thus, the output of open-hearth steel increased 42 percent over 1935 while that of bessemer steel increased 22 percent and of electric furnace steel 43 percent. The bulk (43,114,826 tons) of the total open-hearth output in 1936 was made in basic furnaces.

Of the total output of steel ingots and castings shown above, 47,512,809 gross tons were ingots in 1936 compared with 33,940,445 tons of ingots in 1935.

The bulk of the steel output comes from the contiguous States Pennsylvania and Ohio. In 1936 these two States produced 54 percent of the total steel, 52 percent of the open-hearth steel, and 75 percent of the bessemer-steel production.

Open-hearth steel ingots and castings manufactured in the United States, 1932-36, by States, in gross tons

Steel electrically manufactured in the United States, 1932-36, in gross tons

Year	Ingots	Castings	Total	Year	Ingots	Castings	Total
1932.....	141, 328	99, 783	241, 111	1935 ¹	521, 818	19, 674	541, 492
1933.....	299, 808	121, 395	421, 203	1936 ¹	704, 213	68, 242	772, 455
1934 ¹	349, 095	12, 201	361, 296				

¹ The figures for 1934-36 include only that portion of the steel for castings which was produced in foundries operated by companies producing steel ingots.

The steel-production figure given above for 1936 includes 2,883,622 gross tons of alloy-steel ingots and castings, which represent 6 percent of the total. This figure includes steels in which the minimum of the range specified in any of the elements named exceeds the following percentages: Nickel, over 0.40 percent; chromium, over 0.30 percent; copper, over 0.50 percent; manganese, over 1.65 percent; silicon, over 0.50 percent; molybdenum, over 0.10 percent; vanadium, tungsten, cobalt, titanium, and zirconium, any percent. Although the total steel output increased 40 percent over 1935 in 1936, alloy steels increased 36 percent. Of the total alloy-steel output in 1936, 2,239,885 tons (78 percent) came from basic open hearths, 115,766 tons (4

percent) from acid open hearths, 527,762 tons (18 percent) from electric furnaces, and 209 tons from crucible furnaces.

Production of alloy-steel ingots and castings, 1933-36, by processes, in gross tons

Process	1933	1934 ¹	1935 ¹	1936 ¹
Open hearth, basic.....	1,169,255	1,278,343	1,633,541	2,239,885
Open hearth, acid.....	57,097	34,540	73,400	115,766
Bessemer.....	24,519	53		
Crucible.....	102	103	154	209
Electric.....	296,210	299,236	412,563	527,762
	1,547,183	1,612,275	2,119,658	2,883,622

¹ The figures for 1934-36 include only that portion of the steel for castings produced in foundries operated by companies manufacturing steel ingots.

From the foregoing table it will be seen that the bulk (68 percent in 1936) of the steel made in the electric furnace is alloy steel. Typically, steels with higher alloy content are made in the electric furnace, and steels with lower alloy content are made by the open-hearth and bessemer processes.

Foreign trade in steel.—Responding to greater demands in world markets in 1936, exports of iron and steel products rose materially over those of 1935. Increases occurred in a wide range of semimanufactured and manufactured products. The larger exports of tin plate and terneplate featured the 1936 trade; exports of tin plate and terneplate were 238,881 gross tons valued at \$23,752,978 in 1936 compared with 134,499 tons valued at \$13,021,779 in 1935. The exports of steel ingots, blooms, billets, slabs, and sheet bars, however, declined, amounting to 21,400 tons in 1936 compared with 39,782 tons in 1935. Exports of iron and steel scrap were also lower in 1936, when shipments abroad were 1,936,132 tons compared with 2,103,959 tons in 1935, a decrease of 8 percent. Japan with 1,057,621 tons (55 percent), United Kingdom with 364,874 tons (19 percent), and Italy with 285,126 tons (15 percent) were the principal takers of American scrap in 1936.

Imports for consumption of iron and steel also gained in 1936 over those of 1935. Of the larger items of steel imports, bars, sheets, and structural shapes recorded the largest gains. Foreign purchases of scrap doubled in 1936 over 1935 and amounted to 153,118 gross tons, with Canada the chief supplier in both years.

Iron and steel imported for consumption in the United States, 1935-36

The rise in world output of steel was accompanied by an advance in world production of manganese ore, which attained a new all-time high in 1936. Prices increased during the year, and the market was strong during the closing months. Increases in imports, consumption, domestic production, and prices were noted in the United States. The following table gives the principal statistics of the domestic manganese industry for the past 5 years compared with the annual average for 1925 to 1929, inclusive.

Salient statistics of the manganese industry in the United States, 1925-29 (average) and 1932-36, in long tons

¹ Includes small quantity of miscellaneous ore.

² Imports for consumption.

³ Manganese content.

⁴ Includes small quantity of other manganese alloys.

⁵ Not at liberty to publish.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

The trend in imports and domestic production of manganese ore from 1900 to 1936 is shown graphically in figure 36.

FIGURE 36.—Imports and domestic production of manganese ore, 1900–1936. Statistics on imports shown in the graph represent “general imports” for the period 1900–1933; beginning with 1934 data classified as “general imports” were not available, and the figures plotted for 1934, 1935, and 1936 represent imports for consumption adjusted for changes in stocks in bonded warehouses and are closely comparable with the record for earlier years.

Tariff reductions.—Recent reductions in the tariffs on manganese ore and ferromanganese are given on pages 426, 429, and 434 of Minerals Yearbook, 1936.

Electrolytic manganese.—During 1936 the Bureau of Mines announced the development in the laboratory of a method for producing metallic manganese from its ores by leaching and electrolysis.² Further investigations are being made to adapt the process to commercial uses.

DOMESTIC PRODUCTION

The domestic production (shipments from domestic mines) of manganese ore increased 22 percent in 1936 over 1935. The following table shows details of domestic shipments of various grades of manganese ore from 1932 to 1936.

Manganiferous raw materials shipped in the United States, 1932–36, in long tons

Year	Metallurgical ore (ferrous metallurgy only)				Battery ore	Miscellaneous manganese ore
	Manganese ore (35 percent or more manganese)	Ferruginous manganese ore (10 to 35 percent manganese)	Manganiferous iron ore (5 to 10 percent manganese)	Manganiferous zinc residuum		
1932.....	9,963	15,635	9,799	25,320	7,012	802

¹ 1 producer in Alabama, 1 in Tennessee, and 4 in Virginia shipped both metallurgical and miscellaneous ore, and 1 in Montana shipped both battery and miscellaneous ore.

² Included under "Undistributed."

³ Mills through which all ore was shipped; producers not counted.

⁴ 1 producer in Alabama, 2 in Tennessee, 2 in Virginia, and 1 in West Virginia shipped both metallurgical and miscellaneous ore, and 1 in Montana shipped both battery and miscellaneous ore.

Alabama.—All shipments of manganese ore from Alabama in 1936 were made by J. B. Bynum, who operates the Walnut Grove mine at Walnut Grove, Etowah County. Shipments of metallurgical-grade ore, which amounted to 377 long tons, averaged (dried) 40.68 percent manganese and 2 percent iron, and ore shipped for miscellaneous uses, which amounted to 195 tons, contained 76.45 percent MnO_2 . Shipments of ferruginous manganese ore from Alabama in 1936 totaled 540 tons containing (natural) 30.56 percent manganese; the ore came from Cherokee and Etowah Counties.

Arkansas.—Shipments of manganese from Arkansas in 1936, which totaled 4,557 long tons, came from the Batesville-Cushman district in Independence County and contained (dried) 45.8 percent manganese. In addition, 3,285 tons of ferruginous manganese ore containing (dried) 30 percent manganese were shipped from the same district.

Colorado.—No manganese ore was shipped from Colorado in 1936, but 10,568 long tons of ferruginous manganese ore were shipped from two counties. The Pandora Mines Co., from its operations near Leadville in Lake County, shipped 8,923 tons of ore containing (natural) 17.0 percent manganese and 22.7 percent iron. The Pershing mine near Kerber Creek in Saguache County shipped 1,645 tons containing (natural) 30.4 percent manganese and 8.1 percent iron.

Georgia.—Shipments of manganese ore and ferruginous manganese ore in Georgia in 1936 declined due to the shutting down, during the last 6 months of the year, of the principal producer. Of the 3,821 long tons of manganese ore shipped from Georgia in 1936, all but 60 tons came from the Cartersville district in Bartow County. Although there are several shippers in the district, 3,435 tons containing (natural) 37.72 percent manganese and 7.29 percent iron were shipped by the White Manganese Corporation. The 60 tons shipped from Floyd County came from the Gibson mine near Cedartown and contained (natural) 38 percent manganese.

Shipments of ferruginous manganese ore, which totaled 2,717 tons and contained (natural) 19.14 percent manganese, came from the Cartersville district and from the Gibson mine in Floyd County. In addition, 427 tons of manganiferous iron ore averaging 5.29 percent manganese were shipped from the Cartersville district in 1936. Shipments of untreated iron ore which contained up to 5 percent manganese were also inaugurated during 1936 and are included in the production of iron ore for Georgia. This ore is mined cheaply from small open-cuts and shipped by rail to Birmingham.

Michigan.—The Rogers mine near Iron River in Iron County shipped 9,627 long tons of ore containing (natural) 10.52 percent manganese and 41.34 percent iron, which comprised the total output for Michigan in 1936.

Minnesota.—All shipments of manganese-bearing ores came from the Cuyuna range in Crow Wing County. Shipments of ferruginous manganese ores, which came from the Merritt mine near Trommald, totaled 47,796 long tons containing (natural) 10.85 percent manganese and 33.88 percent iron. Shipments of manganiferous iron ore (840,725 tons) came from four properties (Alstead-Hillcrest, Louise, Sagamore, and Mahnomen) and averaged 7.87 percent manganese and 36 percent iron.

Montana.—Shipments of manganese ore in Montana in 1936 increased 52 percent over 1935. Forty-seven percent of the output was battery-grade ore from the Philipsburg district, and 31 percent was

metallurgical-grade ore, which comprised sintered rhodochrosite and contained 63.59 percent manganese. Shipments for miscellaneous uses accounted for the remainder of the output and contained (natural) 41.4 percent manganese. Shipments of ferruginous manganese ore containing (natural) 19.6 percent manganese were tailings from the battery-ore concentrating mills in the Philipsburg district and amounted to 20,307 long tons.

New Mexico.—Shipments were made from New Mexico in 1936 for the first time in several years. The output came from Sierra County and totaled 170 long tons of ore containing (natural) 34.6 percent manganese and 9.0 percent iron.

Tennessee.—The bulk of the metallurgical ore shipped from Tennessee in 1936, which amounted to 2,679 long tons, came from the operations of the Embree Iron Co. at Embreeville in Unicoi County and averaged (natural) 35.61 percent manganese and 9.49 percent iron. Shipments of ores for miscellaneous purposes came from scattered, small operations in the northeastern counties and totaled 860 tons.

Utah.—Relatively large increases were noted in shipments of manganese-bearing ores in Utah in 1936. Millard and Juab Counties furnished 1,635 long tons of ore which contained (natural) 35.7 percent manganese and 9.4 percent iron. No shipments of this grade were reported in 1935. In addition, shipments of 2,974 tons of ferruginous manganese ore averaging (natural) 30 percent manganese were reported in 1936, compared with 190 tons in 1935.

Virginia.—Shipments of manganese ore from Virginia in 1936 were 1,361 long tons—1,165 tons of miscellaneous ore, containing (natural) 43.09 percent manganese, and 196 tons of metallurgical ore, containing 37.24 percent manganese. The bulk of the total came from Bland County, but shipments were also reported from Giles, Page, and Shenandoah Counties. The old Capola Mountain mine near Woodstock in Shenandoah County was reopened during the year, and a small mill was built and put in operation. Shipments of ferruginous manganese ore, which came from Bland and Giles Counties in 1936, were 874 tons, containing (natural) 25.29 percent manganese compared with 645 tons in 1935.

West Virginia.—Shipments of manganese ore from West Virginia, the first since 1933, totaled 178 long tons, of which 138 tons were metallurgical ore containing (natural) 44.3 percent manganese and 2.2 percent iron and 40 tons were ores for miscellaneous uses containing 69.2 percent manganese dioxide. The entire output came from the Monroe Manganese Mining Corporation Sweet Springs mine near Sweet Springs in Monroe County.

Wisconsin.—Wisconsin shipped 405 long tons of manganiferous iron ore in 1936 which contained (natural) 7.25 percent manganese and 46.75 percent iron. All shipments came from the Cary mine in Iron County.

Puerto Rico.—Shipments of manganese ore from Puerto Rico were 3,010 long tons in 1936 compared with 3,358 tons in 1935. The entire output of the island comes from the mine of the Atlantic Ore Co. about 3 miles from Juana Diaz.

IMPORTS OF MANGANESE ORE

Imports of manganese ore for consumption in the United States in 1936 increased 121 percent over 1935 and were probably the largest on record. Of the 1936 total the U. S. S. R. (Russia) supplied 34 percent.

Manganese ore imported into the United States, 1934-36, by countries

¹ Less than 1 ton.

Stocks.—For the fourth consecutive year stocks of manganese ore in bonded warehouses declined, and at the end of 1936 amounted to 366,381 long tons, containing 181,685 tons of manganese metal. The figure for 1936 is the lowest reported since 1929.

Prices.—Prices of manganese ore according to grade and origin, as quoted by the various trade journals, are for imported ore and (except for battery ore) are on a unit basis. The unit is 1 percent of 1 long ton (22.4 pounds of metallic manganese). Prices of battery-grade ore are quoted on a per-ton basis, with a minimum requirement of manganese dioxide.

The prices in the following table are quoted from the Engineering and Mining Journal:

Domestic prices of metallurgical manganese ore, 1936, in cents per long-ton unit

[C. i. f. North Atlantic ports, cargo lots, exclusive of duty]

	Begin- ning of year	End of year		Begin- ning of year	End of year
Brazilian, 46-48 percent man- ganese.....	\$0.24	\$0.25	Caucasian, 52-55 percent man- ganese.....	\$0.26	\$0.30
Chilean, 47 percent manganese.....	.25	.26	South African: 49-51 percent manganese.....	.26	.30
Indian, 48-50 percent manga- nese.....	.25	.30	44-48 percent manganese.....	.24	.25

According to the Engineering and Mining Journal the prices for chemical (battery) ores during 1936 were as follows: Domestic chemical ores containing 70 to 72 percent manganese dioxide, \$40 to \$45 a ton in carload lots and imported chemical ores containing 80 to 85 percent manganese dioxide, \$45 to \$60 throughout 1936.

CONSUMPTION OF MANGANIFEROUS RAW MATERIALS

The following table shows the indicated consumption of manganiferous raw materials in the United States in 1935 and 1936. The table does not consider differences in consumers' stocks at the beginning and end of the year. As such stocks are largely imported ore and the import figure used in the table is that for "imports for consumption" it is thought that the change in stocks would not be great because the manganese ore may be kept in bond until withdrawn for consumption. The duty is then paid, and the ore is reported as imports for consumption.

Indicated consumption of manganiferous raw materials in the United States, 1935-36

	Ore containing 35 percent or more manganese		Ore and residuum containing 10 to 35 percent manganese		Ore containing 5 to 10 percent manganese

² Partly estimated.

³ Estimated.

Besides the material shown in the foregoing table, 825,272 long tons of iron ore containing 2 to 5 percent manganese presumably were used in the manufacture of manganiferous pig iron in 1936 compared with 575,402 tons in 1935. Figures for imports of this class of ore are not available.

METALLURGICAL INDUSTRY

Although manganese ore is used in both the ferrous and nonferrous metallurgical industries, the bulk is consumed in the manufacture of iron and steel. Most of the ore entering this industry is used in the manufacture of ferromanganese and spiegeleisen, the forms in which manganese usually is added to steel.

Ferromanganese.—In 1936 the following plants produced the domestic output, which increased 47 percent over that in 1935:

Pittsburgh Metallurgical Co., Niagara Falls, N. Y.
 Bethlehem Steel Co., Johnstown, Pa.
 Jones & Laughlin Steel Corporation, Aliquippa, Pa.
 Lavino Furnace Co., Reusens, Va.
 Tennessee Coal, Iron & Railroad Co., Ensley, Ala.
 Carnegie-Illinois Steel Corporation, North Braddock and Etna, Pa.
 Electro Metallurgical Co., Alloy, W. Va.

In addition to the above plants, the Lavino Furnace Co., Sheridan, Pa., made shipments from stock.

Domestic production of ferromanganese during the last 5 years and metalliferous materials consumed in its manufacture are shown in the following table:

Ferromanganese produced in the United States and metalliferous materials consumed in its manufacture, 1932-36

Year	Ferromanganese produced			Materials consumed (long tons)				Manga- nese ore used per ton of ferroman- gane- se made (long tons)

Shipments of ferromanganese in 1936 increased 66 percent over 1935. The trend of shipments during the last 5 years has been as follows:

Ferromanganese shipped from furnaces in the United States, 1932-36

Year	Long tons	Value	Year	Long tons	Value
1932.....	70, 417	\$5, 061, 029	1935.....	194, 627	\$16, 374, 328
1933.....	127, 453	9, 384, 611	1936.....	322, 353	24, 088, 298
1934.....	147, 947	12, 345, 697			

Although there is a slight export trade in ferromanganese, the quantity manufactured in the United States is supplemented by imports. Ferromanganese imported for consumption in 1936 included 532 long tons containing not over 1 percent carbon; virtually all of it came from Norway.

Ferromanganese imported into and exported from the United States, 1932-36

Year	Imports for consumption			Exports ¹	
	Gross weight (long tons)	Manganese content (long tons)	Value	Gross weight (long tons)	Value
1932.....	18, 470	14, 779	\$1, 091, 026	33	\$2, 369
1933.....	39, 693	31, 759	2, 548, 068	47	3, 393

Stocks of ferromanganese in bonded warehouses at the end of 1936 amounted to 9,902 long tons containing 8,177 tons of manganese metal.

The price of ferromanganese, which dropped \$10 and reached \$80.13 per long ton in January as a result of the lower tariff under the trade agreement with Canada, was increased \$5.00 per ton in November.

Prices per long ton of ferromanganese in the United States, 1934-36¹

1934.....	(¹)	45,769	1,099,922				

¹ Not at liberty to publish.

Spiegeleisen was manufactured at the following plants in 1936:

New Jersey Zinc Co., Palmerton, Pa.

Lavino Furnace Co., Reusens, Va.

Tennessee Coal, Iron & Railroad Co., Ensley, Ala.

Carnegie-Illinois Steel Corporation, North Braddock and Etna, Pa.

Keokuk Electro-Metals Co., Keokuk, Iowa.

Most of the spiegeleisen produced in the United States is made from domestic raw materials, but 31,159 long tons of ferruginous manganese ore were consumed in the manufacture of spiegeleisen in 1936.

Imports of spiegeleisen for consumption increased 61 percent in 1936 over 1935. Canada, with 46,051 tons, furnished 89 percent of the total in 1936. The remainder came from Norway and the U. S. S. R. (Russia).

Spiegeleisen imported for consumption in the United States, 1932-36

Year	Long tons	Value	Year	Long tons	Value
1932.....	8,364	\$192,037	1935.....	32,384	\$915,134

1934.....	21,184	595,017			

The price of spiegeleisen containing 20 percent manganese at producers' furnaces has been quoted by trade journals at \$26 per ton for 1934, 1935, and 1936.

Manganiferous pig iron.—Precise data on the consumption of manganiferous ores in the production of manganiferous pig iron are not available; however, 841,557 long tons of domestic ore containing 5 to 10 percent manganese and 825,272 tons containing 2 to 5 percent manganese were shipped in 1936. Foreign manganiferous iron ore (103,079 tons) also was consumed in the manufacture of pig iron. The sources of the foreign ores for the last 3 years are named in the following table. Import figures on ore containing 2 to 5 percent manganese are not available.

Foreign ferruginous manganese ore and manganiferous iron ore consumed in the United States, 1934-36, in long tons

BATTERY INDUSTRY

Shipments of manganese ore by domestic producers to battery makers in 1936 totaled 7,747 long tons and shipments from Puerto Rico 3,010 tons, indicating a consumption of 10,757 tons of domestic materials in battery manufacture. Imported manganese ore also was consumed in the battery industry, but no figures are available for such imports.

MISCELLANEOUS INDUSTRIES

Manganese ore is also consumed in the chemical, ceramic, and glass industries. Certain ores with peculiar physical or chemical properties are required for the manufacture of special articles in these industries.

WORLD PRODUCTION

The following table shows, insofar as statistics are available, the world production of manganese ores from 1932 to 1936 and their average manganese content. Most of the figures are from official statistics of the countries concerned, supplemented by data from semiofficial and other sources.

Manganese ore produced in the principal countries, 1932-37, in metric tons

¹ In addition to the countries listed Belgium is reported to produce a small quantity of manganese ore, but statistics of output are not available. Czechoslovakia reports a production of "manganese ore", but as it has been ascertained that the product so reported averages less than 30 percent manganese and therefore would be considered ferruginous manganese ore under the classification used in this report the output has not been included in the table.

² Approximate production.

³ Exports.

⁴ Shipments by rail and river.

⁵ Data not available.

Brazil.—Exports from Brazil in 1936 were 166,471 metric tons, a large increase over the 60,669 tons exported in 1935. Production was 156,201 tons in 1936.

Cuba.—Output by the Cuban-American Manganese Corporation, the principal producer, amounted to 48,085 metric tons of sintered and unsintered concentrates in 1936; exports from Santiago were 34,813 tons. During 1935 and 1936 this company conducted extensive research and experimental work in an effort to reduce production costs. Changes in operating methods required new machinery, which is being installed, and plans have been made to resume operations early in 1937.

Egypt.—Production of manganese ores in Egypt increased in 1936. Two companies, the Sinai Mining Co. with operations near Abu Zenima and the Hamata Mining Co. near Hamata, furnished the total output.

Gold Coast.—The African Manganese Mines Co. Ltd., which operates at Nsuta, near Tarkwa, Wasaw district, Western Province, is the only producer of manganese ore in Gold Coast Colony. Exports were about 400,000 metric tons in 1936. During the year a Dwight Lloyd plant for sintering part of the ore was erected and put into operation.

British India.—Waterborne exports from India, normally the second largest producer in the world, dropped from 713,557 metric tons in 1935 to 644,197 tons in 1936. These figures do not include exports through Mormugao, which were 165,017 tons in 1935.

Union of South Africa.—Production of manganese ore in the Union of South Africa in 1936 rose to 258,243 metric tons compared with 95,450 tons in 1935. The producing deposits are north of Postmasburg in Griqualand West. The principal producers are the Associated Manganese Mines of S. A., Ltd., and the South African Manganese, Ltd. In May 1936 the railway line was extended from Postmasburg to the Gloucester deposits to permit all-rail haul to Durban, where there are adequate port facilities. Exports during 1936 were 207,841 tons.

U. S. S. R. (Russia).—Output of manganese ore in the U. S. S. R. established a new record in 1936; various estimates place the production between 2,700,000 and 3,000,000 metric tons. The exhaustion of the more easily minable ore at Chiaturi, the principal producing district, has necessitated considerable reconstruction and installation of new equipment for the development of underground mining. The Nikopol mines in the Ukraine, which are becoming more important and at present produce nearly as much as the Chiaturi mines, have been improved by the sinking of new shafts and the installation of electric haulage. Relatively small, but increasing, amounts of manganese ore are coming from the Mazulka mines in West Siberia, where reserves are estimated at 10,000,000 tons. Exports from the U. S. S. R. in 1936 were 605,733 tons compared with 644,874 tons in 1935.

CHROMITE

World production of chromite is consumed principally in the ferrous-metallurgical industry. Active postdepression demands for steel, coupled with accelerated armament activities by the military powers, increased the demand for chromite in 1936. Higher prices, particularly for metallurgical grades, reflected the greater demand, which according to trade reports resulted in a scarcity of first-grade ores available for spot buyers at the end of the year. World production in 1935 established a new all-time peak of 794,000 metric tons. Swelled by large increases in output in Southern Rhodesia and the Union of South Africa, world production in 1936 increased to a new record, although complete production figures are not yet available.

The following table compares salient statistics of the chromite industry in the United States during the last 5 years with the yearly average from 1925 to 1929.

Salient statistics of the chromite industry in the United States, 1925-29 (average) and 1932-36

² Figures not yet available.

Figure 37 shows the trend of domestic consumption and prices during the past 12 years.

FIGURE 37.—Trends in consumption, price, and domestic shipments of chromite in the United States, 1925-36.

DOMESTIC PRODUCTION

The following table shows the production and shipments of chromite in the United States from 1932 to 1936. Shipments in 1936 were reported from Del Norte, Eldorado, Fresno, Napa, San Luis Obispo, and Santa Barbara Counties in California.

Crude chromite mined and shipped from mines in the United States (all from California), 1932-36

Year	Ore containing 45 percent of more chromic oxide			Ore containing 35 to 45 percent chromic oxide			Total value
	Mined (long tons)	Shipped		Mined (long tons)	Shipped		
		Long tons	Value		Long tons	Value	
1932.....	200	155	\$2, 160				\$2, 160
1933.....	879	743	(1)	87	100	(1)	11, 585
1934.....	331	320	(1)	3 10	49	(1)	4, 653
1935.....	66	74	(1)	3 374	3 441	(1)	3 6, 163
1936.....	(1)	(1)	(1)	4 269	4 269	4 \$2, 978	4 2, 978

¹ Included in total value; Bureau of Mines not at liberty to publish figures separately.

² Produced in Montana but not shipped.

³ Includes 52 tons containing less than 35 percent Cr₂O₃.

⁴ A small quality of ore produced and shipped in 1936, containing more than 45 percent Cr₂O₃, may not be shown separately and is included under ore containing 35 to 45 percent Cr₂O₃.

Although all production and shipments in 1936 came from California there was considerable exploration for chromite in Oregon, Montana,

and Washington.¹ Preliminary studies on the treatment of domestic chrome ores were made by the United States Bureau of Mines during 1936.²

IMPORTS ³

Imports of chromite into the United States totaled 324,258 long tons in 1936 compared with 259,063 tons in 1935, an increase of 25 percent. The chromite imported into the United States in 1936 had a chromic oxide content of 43.5 percent. Of the larger imports in 1936, those from New Caledonia had the highest content of chromic oxide (51 percent), while those from Cuba had the lowest (33 percent).

South Africa (Union of South Africa and Southern Rhodesia) was the principal source of our imports in 1936, contributing 37 percent of the total, while Cuba was second with 22 percent. Although Mozambique is listed by the Bureau of Foreign and Domestic Commerce as the principal source of American imports, the ore from this source originates in Southern Rhodesia and the Union of South Africa. The Southern Rhodesian ore moves out of Beira and the South African ore out of Lourenço Marques. According to the United States Shipping Board, Department of Commerce, imports in 1935 from these ports were as follows:

	Long tons
Beira (Rhodesian ore).....	42, 150
Lourenço Marques (Union ore).....	29, 515
Total Mozambique.....	71, 665

The following table shows imports of chromite into the United States, by countries, from 1932 to 1936.

Crude chromite imported into the United States, 1932-36, by countries

CONSUMPTION

Owing to lack of data concerning consumers' stocks, it is impossible to estimate accurately the actual consumption of chromite in the United States. However, the apparent available supply increased from 259,578 long tons in 1935 to 324,527 tons in 1936 and was greater than in any year since 1930.

The increase in consumption of chromite during 1936 reflects increased activity in the steel industry, the principal consumer. The domestic automobile industry, one of the principal users of alloy steels and chromium plating, increased its output 13 percent over 1935, making 4,454,535 cars in 1936 or the largest number since 1929. The building-construction industry uses stainless steel for decorative purposes and large quantities of chromium-plated plumbing fixtures. Activity in this field improved materially over that in 1935.

The following table shows the apparent available supply of chromite in the United States from 1932 to 1936.

Domestic sales, imports, and apparent available supply of crude chromite in the United States, 1932-36, in long tons

Year	Sales from domestic mines	Imports	Apparent available supply	Year	Sales from domestic mines	Imports	Apparent available supply
1932.....	155	89, 143	89, 298	1935.....	515	259, 063	259, 578
1933.....	843	116, 511	117, 354	1936.....	269	324, 258	324, 527
1934.....	369	192, 297	192, 666				

USES

Industrial uses of chromite fall into three groups, which are in order of importance: Metallurgical, refractory, and chemical. Increasing quantities are being absorbed in chemical uses.

METALLURGICAL

Alloy steels.—Chromium is one of the principal elements used in the manufacture of alloy steels. For this purpose most of the chromite is converted to ferrochromium in the electric furnace before it is added to the steel bath, although one domestic concern makes chromium alloy steels in the electric furnace directly from alloy-steel scrap, mild-steel scrap, and chromite. Lippert⁴ has described a method of making stainless-steel castings by the reduction of chromite in a hollow-electrode furnace.

Steady advance in the field of alloy steels and irons has broadened their market and thus increased consumption of chromite. Steel⁵ has listed 300 concerns supplying alloys and alloy steels for industrial uses. Chromium in varying quantities, either alone or combined with other alloying elements (including aluminum, columbium, copper, manganese, molybdenum, nickel, nitrogen, selenium, silicon, sulphur, titanium, tungsten, vanadium, and zirconium), enters into the manufacture of a wide variety of alloy steels designed for special purposes. Although figures for the production of stainless iron and steel are not available, it has been estimated⁶ that the tonnage in 1936 was double that in 1935. Twelve-car streamline railroad trains constructed of stainless steel were in operation in 1936. A new alloy containing 35 percent chromium and 7 percent aluminum is said to be suitable for continuous service at 2,300° F. Most of the corrosion- and heat-resisting steels manufactured in the past were covered by the Strauss or Haynes patents, which either expired in 1936 or will expire in 1937. Although these are the basic patents, others will exert a definite influence in this field.

Of interest during 1936 was the continued development of low-alloy, high-tensile steels. These steels have been divided⁷ into three general types: Chromium steels, nickel steels, and manganese steels. Of the several types of chromium steels, the two best known in the United States are those containing 0.50 and 1 percent chromium.

Chromium plating.—In recent years⁸ chromium plating has had a wide field of uses and has become important industrially, but the amount of raw material consumed is small owing to the thinness of the layer of metal deposited.

In a decision of the United States Circuit Court of Appeals for the Second District, dated September 21, 1936, the court found that patent 1581188 was invalid.

⁸ See also *Minerals Yearbook*, 1935, p. 527, and *Minerals Yearbook*, 1936, p. 481.

REFRACTORIES

Chrome refractories have been discussed in detail in earlier chapters of this series. Chrome-magnesite roofs have been installed successfully in European open-hearth furnaces for steel melting; higher temperatures are said to be attainable when they are used. Unburned, basic, refractory brick continued to make progress and is finding extensive use. Sullivan^{*} has discussed the application and performance of various refractory materials, including chrome refractories.

According to the Bureau of the Census, production of chrome and magnesite brick was 12,112,000 brick valued at \$3,424,726 in 1935 compared with 10,640,000 brick valued at \$3,091,573 in 1934; stocks were 3,228,000 brick at the end of 1935 compared with 3,336,000 at the end of 1934.

According to trade journals the price of chrome brick during 1936 was \$45 per short ton.

CHEMICALS

In addition to the chromite used in the manufacture of chromic acid for electroplating, considerable chromite is consumed in chemicals used principally in the dyeing, tanning, and pigment industries.

PRICES

Prices of chromite quoted in domestic trade journals are for imported ore and are given in dollars per long ton c. i. f. North Atlantic ports. According to Steel, chromite containing 48 percent chromic oxide was quoted at \$19.25 at the beginning of 1936. Price increases during the year brought the figure to \$21 late in December. Ore with a lower chromic oxide content usually brings a lower price.

WORLD PRODUCTION

Complete data are not yet available on world output of chromite in 1936, but increases in exports and preliminary figures for production indicate that world production increased materially over that in 1935 and established a new record high. Southern Rhodesia and the Union of South Africa recorded large increases in output; these two countries, the U. S. S. R. (Russia), and Turkey are the four major producers. Activities in Turkey continued to expand production, and export figures indicate that output reached a new record in 1936. The following table shows available statistics on world production from 1932 to 1936, inclusive.

^{*} Sullivan, John D., *Refractories in Metallurgical Industries*: Jour. Am. Ceram. Soc. vol. 19, no. 8, 1936 pp. 213-233.

WORLD TRADE

Chromite is an important commodity in world trade. Except for the U. S. S. R. (Russia) the principal producing countries consume only small quantities and the major consuming countries produce only a small fraction of their requirements. World exports in 1936 probably were the largest on record and are estimated at 700,000 metric tons. Southern Rhodesia, with a large increase, was the principal exporter followed by Turkey and Union of South Africa.

Figures on imports of chromite into consuming countries in 1936 are not yet complete, but available data indicate that the three principal importing countries, in order of quantity, were the United States, Germany, and Sweden.

A brief summary of the activities in the principal chromite producing and consuming countries, other than the United States, follows.

Canada.—Figures on the production of chromite in Canada during 1936 are not yet available, but a small quantity was produced from the Thetford-Black Lake area of the Eastern Townships of Quebec. Chromite was mined also near Obonga Lake, northwestern Ontario, by the Chromium Mining & Smelting Corporation.

Cuba.—The entire Cuban output moves to the United States; imports into the United States from Cuba in 1936 were 71,086 metric tons compared with 48,509 tons in 1935. Cuban ores are low grade and used principally for refractories.

Cyprus.—The Cyprus Chrome Co., Ltd., continued to develop its chromite deposits on the lease at Troodos.

France.—France depends on foreign sources for its domestic requirements. Imports for the first 11 months of 1936 were 43,666 metric tons.

Germany.—Germany produces no chromite. Imports were 123,375 metric tons in 1936 compared with 95,440 tons in 1935. Of the German imports in 1936, 53 percent came from Turkey and 30 percent from the Union of South Africa.

India.—Production of chromite in India has been increasing, but actual figures for 1936 are not yet available. Waterborne exports declined slightly from 26,472 metric tons in 1935 to 25,389 tons in 1936, however these figures do not include exports through Mormugão which amounted to 15,399 tons in 1935.

New Caledonia.—New Caledonia is one of the important sources of chromite, and preliminary figures indicate that the output in 1936 was 47,837 metric tons. Exports were 78,266 metric tons in 1936 compared with 73,791 tons in 1935. Reductions in the mining tax on chromite were made late in 1936, apparently to encourage the milling of chrome ore in the colony.

Norway.—Imports of chromite into Norway in 1936 were 41,953 metric tons, and exports of ferrochromium were 11,031 tons.

Philippine Islands.—Exploration in the Philippines during recent years appears to have developed a considerable reserve of chromite. Imports of chromite into the United States from the Philippine Islands in 1936 were 5,066 metric tons containing 50 percent Cr_2O_3 .

Southern Rhodesia.—The output in 1936 was 183,395 metric tons, an increase of 73 percent over 1935 and the largest since 1930. Southern Rhodesia has again established itself as the principal world producer of chromite.

Southern Rhodesian ore moves through the Port of Beira in Portuguese East Africa for shipment to world markets, and all ore moving through Beira originates in Rhodesia. Chrome ore exported from Beira totaled 185,942 metric tons in 1936 compared with 103,550 tons in 1935.

Sweden.—Imports of chromite into Sweden increased from 41,193 metric tons in 1935 to 50,689 tons in 1936. Exports of ferrochromium from Sweden were 11,342 metric tons in 1935.

Turkey.—Production of chromite in Turkey continued at the high level reached in 1935. Virtually all ore is exported as there is little or no domestic demand; exports in 1936 were 149,642 metric tons, a small increase over the 145,723 tons exported in 1935. The newly discovered deposit near Ergani is being developed and will be in production early in 1937.

Union of South Africa.—Production of chromite in the Union of South Africa in 1936 reached a record figure of 173,141 metric tons compared with 90,431 tons in 1935, an increase of 92 percent. Large increases in output during recent years have made this country one of the chief sources of chromite. Exports in 1936 were 99,242 metric tons, a large increase over the 60,438 tons (revised figure) exported in 1935.

A new deposit on farm Jagdlust No. 333 in the Lydenburg district was being developed during the year. The seam, which is usually about 5 feet thick, comprises friable ore and is exposed by trenching at 150-foot intervals for a distance of 3,000 feet.¹⁰

Chromite from the Union of South Africa moves to world markets through the port of Lourenço Marques, Portuguese East Africa, and all exports from Lourenço Marques originate in the Union of South Africa. During 1936 there were exported through Lourenço Marques 90,160 metric tons of chromite compared with 96,355 tons in 1935. Of the 1936 shipments, 33,813 tons were consigned to the United States.

U. S. S. R. (Russia).—The U. S. S. R. (Russia) is one of the largest producers of chromite. Output has been increasing and in 1935 amounted to 177,900 metric tons; figures for 1936 are not yet available. Exports are small, as the bulk of the output is consumed in domestic industries.

NICKEL

For the second consecutive year world production of nickel has broken all previous records, reflecting the constantly increasing popularity of this metal in its exceedingly diversified uses. Estimated world deliveries of nickel in all forms from all sources during 1936 were 100,000 short tons compared with 80,000 tons in 1935 and 68,000 tons in 1929. Search for new deposits to share in this unprecedented demand continued; and several of unproved size were discovered, chiefly in Canada. Other previously known deposits in many countries, notably Canada, Finland, Japan, and the U. S. S. R. (Russia), were developed to the producing stage. Canada, however, continued to supply about 90 percent of the world's nickel requirements. Productive capacity in the Sudbury district was increased about 30 to 40 percent by the two producing companies, so that full-time operations now will permit an annual output of about 128,000 short tons of nickel. Manufacturers of transportation equipment, particularly the automotive industry, continued to be the principal users of nickel.

Quotations for electrolytic nickel cathodes remained unchanged at 35 cents per pound throughout 1936.

Aside from small quantities of secondary nickel recovered from scrap-nickel anodes, nickel-silver and copper-nickel alloys (including monel metal), and smaller quantities recovered in copper refining, the United States is totally dependent on imports for its nickel supplies.

Capacity of the Huntington (W. Va.) rolling plant of the International Nickel Co., Inc., was expanded by the addition of another 25-ton open-hearth furnace, and the laboratory and office buildings were enlarged.

USES

The uses of nickel are far too numerous to list here. Alloyed with iron and many other nonferrous metals or employed as metallic nickel, it meets the peculiar physical, chemical, and æsthetic qualities required in literally thousands of uses. Its ability to impart great strength and corrosion resistance to alloys is its outstanding characteristic. Other uses depend on the magnetic qualities found in alloys containing certain percentages of nickel. Manufacture of

transportation equipment, particularly automobiles, continues as the dominant field of nickel consumption. For strengthening steels used in such highly stressed parts as axles, shafts, gears, connecting rods, valves, crankshafts, and steering knuckles and arms, nickel is generally specified, commonly with one or more other alloying elements. An important recent development is the expanding use of nickel in cast iron;² many automotive manufacturers now specify this material for crankshafts and camshafts. In busses, trucks, and railroad rolling stock (both passenger and freight) the tendency to reduce deadweight to a minimum has accelerated consumption of nickel steels and other nickel alloys to save weight without sacrificing strength and safety. High strength-to-weight ratios and corrosion resistance of nickel alloys continue to make them suitable for highly stressed vital parts of ships and airplanes.

Other important industrial uses of nickel alloys are in equipment for petroleum producing and refining, mining, road and building construction, and food and beverage preparation and in the chemical, electric, textile, agriculture, pulp and paper, and steel industries.

Undoubtedly acceleration of rearmament throughout the world has furnished an important outlet for nickel, as it is almost indispensable in the manufacture of munitions, armor plate, and other mechanized equipment used in modern warfare.

Considerable progress was made in bright nickel plating. New developments in this field have been summarized by Johnson.³

A detailed discussion of trends in nickel consumption may be found in *The Nickel Industry in 1936*, by Robert C. Stanley, President, International Nickel Co. of Canada, Ltd.

WORLD PRODUCTION

¹ Data not yet available.

² Estimate included in total.

³ Byproduct in electrolytic refining of copper.

Canada.—For years production from the Sudbury district in Ontario has yielded about 90 percent of the world output of nickel, and reserves are adequate to furnish similar proportions for decades to come. Output in 1936 was the greatest ever recorded in Canada's

¹ Merica, Paul D., *Progress in the Improvement of Cast Iron and the Use of Alloys: Howe Lecture delivered before 147th Meeting of Am. Inst. Min. and Met. Eng.*, New York, Feb. 18, 1937.

mining history: 169,737,864 pounds valued at \$43,878,413 were produced, compared with 138,516,240 pounds valued at \$35,345,103 in 1935. Two companies, the International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd., continued to be the main producers.

The International Nickel Co. of Canada, Ltd.,⁴ operated at capacity throughout 1936 and completed another expansion program by which its capacity was raised by about a third to 10,000 tons of nickel per month. Two mines, the Frood and Creighton, produced 4,299,329 short tons of ore; the former yielded 3,408,956 tons and the latter 890,373 tons. The Frood now has enough stopes in operation to yield 13,000 tons of ore per day. The concentrator treated 3,317,988 tons of ore; construction work finished during the year now permits a daily throughput of 11,000 tons, an increase of a third over its previous capacity. The Port Colborne nickel refinery, which operated full time, produced 103,860,757 pounds of nickel; its capacity was increased 50 percent during the year. Sales of principal products by the company increased as follows from 1935 to 1936, respectively: Nickel in all forms, from 64,925 to 84,464 short tons; copper from 116,505 to 132,977 tons; and platinum from 128,874 to 220,980 ounces. From 1932 to 1936, inclusive, total sales of copper averaged 1.73 pounds per pound of nickel sold and sales of platinum 1.14 ounces per 1,000 pounds of nickel sold.

Falconbridge Nickel Mines, Ltd.,⁵ was forced to shut down its smelter in September owing to a fire at the Government plant supplying power, but the company refinery in Kristiansand, Norway, continued operations at capacity throughout the year, and sales of nickel increased from 10,829,865 pounds in 1935 to 11,252,893 in 1936. Copper sales were 5,149,215 pounds in 1936, compared with 5,129,483 in 1935. Ore treated totaled 327,783 tons in 1936, of which 126,782 tons were milling ore and 201,001 tons smelting ore. The ore averaged 1.9 percent nickel and 0.92 percent copper. An extensive expansion program was completed in December, in both the Ontario and Kristiansand works, which will permit production and treatment of 36,000 tons of ore monthly. For 12 months of operation and at 1936 metal yields the annual productive capacity would be about 15,000,000 pounds of nickel and 7,000,000 pounds of copper. New mine development proved up considerably more ore than was taken out in 1936; ore reserves were 5,331,076 tons at the end of 1936, compared with 4,059,475 tons at the close of 1935.

Complete details concerning new developments at both International Nickel and Falconbridge operations were presented by Hubbell.⁶

Other small producers were Cuniptau Mines, Ltd., with an output of some copper-nickel matte from its smelter in the Temagami district, Ontario, and the B. C. Nickel Mines, Ltd., which produced nickel-copper ore from development work at its property at Choate, British Columbia. According to widely circulated reports, the latter company made two shipments of ore (500 and 1,000 tons) to Japan for testing which assayed 4 to 5 percent nickel and about 2 percent copper.

Diamond drilling has proved up what appears to be a sizeable ore body on the property of Denison Nickel Mines, Ltd., in the Sudbury Mining Division.⁷ Extensive development work is planned.

⁷ Northern Miner, Jan. 14, 1937, sec. 3, p. 34.

Other discoveries were reported near Lake Athabasca, Saskatchewan,⁸ and near Kenora, Ontario.⁹

Finland.—Prospecting and development of the Petsamo deposits by the Mond Nickel Co., Ltd., continued throughout the summer of 1936 with what were said to be favorable results. Considerable equipment was transported to the fields, and some 50 kilometers of road were built. The company plans to construct an electric railway from the ore fields to Liinahamari, a distance of about 50 kilometers, and a survey of the route was begun. Construction of a hydroelectric power plant on the Pats River is another part of the project. A shipment of 400 tons of ore for testing purposes from Petsamo to Swansea was reported.¹⁰

India, British.—The Burma Corporation, Ltd., continued to ship nickel-bearing speiss from its mines in the Northern Shan States.

Japan.—Of considerable importance to the Japanese was the formation of the Japan Nickel Co. in 1936, with an authorized capital of 5,000,000 yen (about \$1,500,000). Detailed plans have not been published, but it is stated that a small plant with an annual capacity of 350 to 400 tons of nickel will be ready to operate by April 1937. Ore will be drawn from deposits in Gumma Prefecture, which are said to contain about 30,000,000 metric tons averaging 0.33 percent nickel.¹¹

Netherland India.—Samples of ore from the recently discovered Boeloe-Balang nickel deposits in central Celebes were sent to Europe for testing. The main ore body is reported to comprise about 320,000 tons of about 1.96 percent nickel, above which are 500,000 tons of weathered material some 1 to 5 meters thick which assays 1 to 1.5 percent nickel.¹²

New Caledonia.—The first important shipment of nickel from New Caledonia to Japan was made when a cargo of 3,000 tons of ore was loaded on the *Manju Maru* at Kua in October. The ore came from the Ouli-Ouli mine, which is owned and exploited by the Japanese.

The mining operations of the Société Calédonnickel were reported late in 1936 to be at capacity; three mines were producing (the Guerioum Nos. 215, 70, and 174), and monthly production averaged about 4,500 metric tons. Another mine, the C. F., will begin production soon.¹³

Norway.—The refinery of Falconbridge Nikkelverk, Aktieselskap, at Kristiansand, operated at capacity through the year on matte shipped from the Falconbridge smelter near Sudbury, Ontario, Canada. Enlargement of the refinery to permit an annual output of some 7,000 tons of nickel was completed during the year.

United Kingdom.—The Clydach nickel refinery of the Mond Nickel Co., Ltd., produced 18,152 tons of nickel in the form of pellets and 1,281 tons of nickel in salts in 1936. Productive capacity was increased to an annual output of 21,000 tons, and late in the year the company opened its new research and development laboratory at Birmingham. An excellent account of the history of nickel processing in the United Kingdom is now available.¹⁴

¹⁴ Henry Wiggin & Co., Ltd., One Hundred Years of Progress: Centenary pub.

U. S. S. R. (Russia).—An easily movable nickel smelter was completed at Rezh about 80 kilometers from Sverdlovsk in the Urals late in 1936, and the first matte was produced in November. It is proposed to operate the plant on the many small nickel deposits scattered through the Urals. Refining of the matte will be done at the Ufaiei plant.

Mining is said to have begun on the reputedly extensive nickel deposits near Monchegorsk above the Arctic Circle and some 600 miles north of Leningrad.¹⁵

COBALT

World production of cobalt is centered in the Belgian Congo, Northern Rhodesia, Canada, and Morocco, and for many years there has been close agreement among the producers as to production and marketing. This was culminated by the formation of the Cobalt Association in October 1934 which comprised principal producers in the Belgian Congo, Northern Rhodesia, Canada, and Morocco. The Association of German Cobalt Producers joined it in 1935. The agreement, which was due to expire in August 1936, was renewed for 5 years, an indication of its successful functioning in the past.

Although complete statistics on production are not available (the principal gap during the past few years being in the Belgian Congo output), it is apparent that an all-time record for world production of cobalt was established in 1936.

Prices.—Quoted prices for cobalt ore are in cents per pound of contained cobalt in carload lots f. o. b. shipping point in Ontario and range from 40 cents for ores containing 8 to 9 percent Co to 55 cents for those assaying over 14 percent. These quotations remained unchanged throughout 1936, but the keen demand for cobalt ores resulted in sales at considerably higher figures. The New York contract price for cobalt metal, less quantity discounts, remained at \$1.25 throughout the year, while the London price stood steady at 5s. 3d. The spot price on 500-pound lots in London strengthened from 5s. 3d. in January to 6s. in May and to 7s. in November. The domestic quotation for black oxide (70 to 71 percent Co) opened 1936 at \$1.39 to \$1.49 per pound, was reduced 10 cents per pound on January 20 when the Canadian trade agreement became effective (reducing the duty 50 percent, from 20 to 10 cents per pound), and was raised to \$1.41 to \$1.51 early in May (where it remained the rest of the year).

The London quotation of 4s. 10½d. to 5s. in the early part of 1936 was raised in June (5s. to 5s. 6d.) and again in November (5s. 4½d. to 5s. 7½d.). The extension of the cobalt cartel doubtless helped to strengthen prices.

DOMESTIC PRODUCTION

Reported occurrences of cobalt minerals are numerous, but the size and grade of these deposits are such as to preclude their commercial development under prevailing prices. A recent Government report presented details concerning mineral supplies in the Boulder Dam area, and conclusions concerning possible supplies of cobalt in the region (mainly in the Yellow Pine or Goodsprings district in southern Nevada, from which small shipments of cobalt ore were made in 1922) were as follows:¹⁶

¹⁵ Bureau of Foreign and Domestic Commerce, Metals and Minerals: Jan. 29, 1937, and Dec. 9, 1936.

¹⁶ U. S. Geological Survey, Mineral Resources of the Region Around Boulder Dam, Bull. 871, 1936, p. 87.

* * * Without much doubt several hundred tons of material containing about 2 percent of cobalt could be readily produced from existing explorations, but conditions do not warrant the hope for a large reserve.

A western electrolytic-zinc plant recovered 6.438 tons of residues in 1936 which contained 4.084 percent Co, but no shipments were made.

Thus the United States has been wholly dependent for many years on imports for its supplies of cobalt.

USES

The principal uses of cobalt are somewhat evenly divided between the metallurgical and ceramic fields. Metallurgical uses are for high-speed cutting steels, for making stellite alloys (cobalt and chromium, commonly with small amounts of other metals) used for cutting metals at high speed, and for making permanent magnets. Small quantities of the metal are also used as a binder in making cemented tungsten carbides. Announcement was made early in 1936 that a new nickel-cobalt-aluminum alloy "Alnico" had been developed by the General Electric Co. Permanent magnets made of it are able to lift as much as 60 times their own weight when designed for that purpose. A noteworthy development in cobalt plating during 1936 was the discovery that the use of small quantities of cobalt with other chemicals in nickel-plating solutions permits production of bright nickel electrodeposits as an undercoating for later chromium plating.¹⁷

¹⁷ Weisberg, Louis, Use of Cobalt-Nickel Solutions to Produce Bright Electrodeposits: Steel, July 13, 1936, p. 43.

The principal use of the oxide is in the ceramic industry, where its coloring properties are utilized in fine china and glassware. Other compounds of cobalt are employed as driers in paint and varnish.

WORLD PRODUCTION

¹ Data not available.

² Year ended June 30 of year stated.

Belgian Congo.—Production of cobalt by the Union Minière du Haut Katanga continued and presumably increased to correspond with the larger copper output.

Canada.—The Ontario Department of Mines reported total production of cobalt (including metal and metallic content of oxides sold and of ores and residues exported) at 881,995 pounds valued at \$801,857 in 1936 compared with 681,419 pounds valued at \$512,705 in 1935. Exports of cobalt metal, alloys, oxides, salts, and ores were valued at \$842,947 in 1936 compared with \$541,554 in 1935. The Nipissing Mining Co., Ltd., shipped most of the cobalt ore, but the Agaunico mine became an important shipper during the last half of the year. It was reported that the Nipissing company, while sinking along an old cobalt vein, ran into a sizable deposit late in 1936.¹⁸ Smaller shipments were made by many other operators and numerous lessees. Much of the cobalt production from this camp now comprises small clean-up operations underground in areas where cobalt-bearing ground was left in the earlier silver-boom days. In addition, considerable cobalt is recovered by hand-sorting at old waste dumps.

By far the larger part of the cobalt ore or concentrates produced in this district in 1936 was exported as such; the remainder was shipped to the Deloro smelter for processing into metal or oxides (principally the latter). Cobalt contained in silver ores shipped from the O'Brien mine near Cobalt is also recovered at Deloro.

Morocco.—The Société Minière de Bou-Azzer et du Graara continued development of its mine at Bou-Azzer about 180 kilometers southeast of Marrakech in the Anti-Atlas and shipped cobalt ore to Europe throughout 1936. Cobalt production in Morocco totaled 371 metric tons in 1936 compared with 445 tons in 1935. A detailed microscopic study¹⁹ revealed that the principal cobalt mineral is skutterudite (CoAs₂), associated in places with sefflorite (orthorhombic

CoAs_2) and with löllingite (FeAs_2). Erythrite is found at the outcrop. In places the ore carries considerable gold.

Northern Rhodesia.—Production of cobalt in Rhokana cobaltiferous copper ore was 461 metric tons in 1936 compared with 417 tons in 1935. A new selective flotation process was evolved by the Rhokana Corporation for treating the cobalt-copper ore from the Nkana mine, by which converter slag lower in copper and higher in cobalt is produced from a separate cobalt concentrate.²⁰ United States Patent 2058126 was granted to F. L. Bosqui of Nkana for a process by which ferrocobalt is produced by electrolytic treatment of a cobalt-iron-copper alloy.²¹

MOLYBDENUM

Probably no other metal has experienced as phenomenal a growth in output during the past decade as molybdenum; molybdenite is one of the few common ferro-alloying minerals of which the United States has ample supplies for its own needs. During the past decade, domestic production increased from 1,143 short tons of molybdenum in concentrates in 1927 to 8,593 tons in 1936, or roughly 750 percent. This remarkable increase has been due to the growing realization that alloy steels and more recently alloy irons containing small amounts of molybdenum can better meet the ever more rigid and exacting specifications of manufacturers of steel and iron equipment for myriads of special uses.

In recent years the United States has produced 75 to 90 percent of the world output of molybdenum. The relatively small production in foreign countries comes mainly from Norway and Mexico. Exports of molybdenum from the United States are not known exactly, since they are not separately classified in trade statistics, but they are believed to comprise 50 to 75 percent of the domestic production.

During 1936 a construction program by which the productive capacity of the principal producer, Climax Molybdenum Co., will be almost doubled was virtually completed. Of considerable importance, also, was the entry of Utah Copper Co. as a producer of molybdenite

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce. Figures on domestic production compiled by H. W. Davis, of the Bureau of Mines.

concentrates from its open-pit operation at Bingham. In an emergency this expansion of productive capacity might prove of inestimable value to the United States, for in certain vital uses it has been found that molybdenum can substitute for other alloying metals of which domestic supplies are deficient for even normal requirements. Even with operations scaled up to developed capacity, the known reserves of molybdenum are adequate for at least several decades.

Prices.—Prices for molybdenite concentrates carrying 90 percent MoS_2 were quoted nominally by the Engineering and Mining Journal at 42 cents per pound of contained MoS_2 throughout 1936. London prices for the same grade of concentrates were quoted in January 1936 at 34s per long ton unit (22.4 pounds of MoS_2) and strengthened to 35s in February and to 37s in March, where they held until December when the quotation rose to 39s. This price rise was equivalent to an increase of from 38 cents per pound of MoS_2 in January to 43½ cents in December.

DOMESTIC PRODUCTION

Arizona.—The Arizona Molybdenum Corporation maintained steady operations at its property on Copper Creek near Mammoth, Pinal County, and treated 87,021 short tons of ore during 1936, from which 1,165 tons of concentrates containing 1,320,891 pounds of molybdenum were recovered.

The Molybdenum Gold Mining Co., a subsidiary of the Molybdenum Corporation of America, continued to mine complex ore from the oxide zone in the Mohawk and New Year claims near Mammoth, from which gold, silver, lead, molybdenum, and vanadium were recovered in its flotation mill. Near by the Mammoth-St. Anthony, Ltd., produced similar ore from its Mammoth mine, which was treated in the Molybdenum Gold Mining Co. mill. Cooperative work between the United States Bureau of Mines, the Missouri School of Mines, and the Mammoth-St. Anthony, Ltd., by which successful flotation methods for treating these complex ores were developed, was described by Clemmer and Cooke.¹ Recent developments in the area, including a brief geologic description of the properties together with an outline of milling methods, were summarized by Huttl.² The capacity of the

mill is reported to have been increased from 200 to 300 tons of ore per day.

Colorado.—The Climax Molybdenum Co., world's largest producer of molybdenum, operated its mine and mill at capacity throughout 1936, having mined 1,994,926 tons of ore from which 14,211 tons of concentrates containing 15,216,806 pounds of molybdenum were recovered. The phenomenal growth in production by this company is indicated by the following table:

*Molybdenum (element) contained in concentrates produced from the Climax deposit, Colorado, 1918-36*¹

¹ None produced, 1920-23, inclusive.

The elaborate construction program recently undertaken by the company, leading toward an increase in productive capacity from about 4,000 to some 10,000 short tons of ore per day, and addition of modern surface housing for employee welfare were virtually completed late in 1936, although it was expected that full operations at the new rate would not be reached until the spring of 1937. Detailed descriptions of recent developments at Climax were presented by Coulter,³ and a lengthy article⁴ giving an account of the growth of this great enterprise also appeared recently. As an additional step in its progressive program, Climax started construction of a new laboratory in Detroit, Mich., to be used for research in connection with sales-promotion work.⁵

New Mexico.—The Molybdenum Corporation of America operated its mine and mill, some 7 miles east of Questa along the Red River, continuously throughout 1936. Most of the ore treated was mined by leasers from older parts of the property, company miners having been engaged principally in development work on a lower level just being opened up. The ore is relatively high grade and the tonnage treated comparatively low.

Utah.—A notable development in the domestic molybdenum industry in 1936 was the successful recovery of molybdenite from copper ores mined and treated by the Utah Copper Co. from its huge open-pit operation at Bingham. The annual report of the Kennecott Copper Corporation describes this new development as follows:

The principal metallurgical development of the year was the inauguration of the production of molybdenite as a byproduct from the concentration of certain copper ores. Research in the separation of this mineral had been under way for many months, but it was not until the last quarter of the year that production was begun in a small way. Marketing of the product was commenced in December. While the outlook for earnings from this new source is promising, no definite evaluation of the amount thereof can be made at this time.

³ Coulter, W. J., *Climax: The Explosives Engineer*, November 1936, pp. 323-329. Coulter, W. J., *Molybdenum Operations at Climax: Mining Cong. Jour.*, January 1937, pp. 54-56.

⁴ *Fortune*, Element Number Forty-Two: October 1936, p. 105.

⁵ *Iron Age*, June 4, 1936, p. 95.

A later report,⁶ quoting D. D. Moffat, general manager of Utah Copper Co., stated that the value of the molybdenite recovered is only a few cents to the ton of crude copper ore treated; and E. T. Stannard, president of Kennecott Copper Corporation, later released a statement⁷ that production was running at about 700,000 pounds of MoS₂ per month. This amounts to 420,000 pounds of Mo monthly or about 5,000,000 pounds per year. Maintenance of operations at a rate permitting this production would be contingent on conditions in the copper market; fluctuations in copper production would result in fluctuations in molybdenite output.

Washington.—The Deertrail Monitor Mining Co. (409 Metals Bldg., Spokane) did considerable development work at its Monitor mine near Fruitland, Stevens County, installed a 50-ton mill, and started operating late in December. Crude ore mined during 1936, mainly in development work, amounted to 2,000 tons, the ore running about 1 percent MoS₂. Only 200 tons were treated, from which 2 tons of concentrates were recovered.

Installation of a 50-ton concentrating plant and mining of 500 tons of molybdenite ore were reported by Copper Mining Co. (Goose Prairie, Wash.), at its property near Yakima, Yakima County. The company expects to be in production by the summer of 1937.

IMPORTS AND EXPORTS

Imports of molybdenum or compounds of molybdenum are negligible. Exports of molybdenum, principally in the form of concentrates, are a very important item in the domestic molybdenum industry. Exact figures are not available, since molybdenum is not separately classified in export statistics; but it is reasonably certain that 50 to 75 percent of the domestic production of concentrates is exported. In 1936 roughly two-thirds of the total United States production of concentrates was shipped abroad.

Molybdenum ore and concentrates, ferromolybdenum, molybdenum metal and powder, calcium molybdate, and other compounds and alloys of molybdenum imported for consumption in the United States, 1927-36

1931.....	210, 766	213, 660	1936.....	49	213

USES

Molybdenum is used principally in the iron and steel industry for making special alloy steels to be used under high fatigue loads, scorching temperatures, tremendous pressures, or severely corrosive conditions. It may be employed alone as an alloying material but commonly is added along with such other well-known ferro-alloy metals as chromium, nickel, tungsten, manganese, and silicon. Use of molybdenum high-speed tool steels for cutting metal at high speeds,

⁶ Engineering and Mining Journal, April 1937, p. 203.

⁷ Engineering and Mining Journal, Metal and Mineral Markets, May 13, 1937, p. 3.

and therefore high temperatures, is apparently expanding;⁸ such steels contain approximately 8 percent molybdenum and 2 percent tungsten, along with small amounts of chromium, vanadium, or possibly cobalt. The manufacture of automobiles, trucks, busses, airplanes, railroad equipment, and equipment for petroleum producing and refining constitute important outlets for the use of molybdenum-bearing alloys. Increasing quantities of this metal have recently gone into the manufacture of cast iron which must withstand certain severe requirements. Detailed discussions of the uses of molybdenum in steel and iron and of the many applications of these products in industry may be found in the numerous pamphlets issued by Climax Molybdenum Co.⁹

A promising use for molybdenum is in a new method for bright-plating zinc developed by Grasselli Chemical Co.¹⁰ A new process for the electrodeposition of molybdenum was also announced during the year.¹¹

WORLD PRODUCTION

Although at least 80 percent of the molybdenum output of the world is produced by the United States, small tonnages are mined in a few foreign countries.

World production of molybdenum ores and concentrates,¹ 1932-36, in metric tons

³ Less than 1 ton.

⁴ Exports.

Canada.—A 150-ton flotation mill was installed at the property of the Phoenix Molybdenite Corporation in Renfrew County, eastern Ontario, and considerable development work was done on the mine, ore from which is said to run 1 to 1.5 percent MoS₂.¹²

Mexico.—The Mexican output of molybdenum comes entirely as a byproduct from the Greene Cananea Copper Co. operation, where labor difficulties caused cessation of work during part of the year.

Norway.—Production comes entirely from the Knaben mine near Kristiansand; exports of molybdenite were 745 tons of concentrates in 1936 compared with 627 tons in 1935.

TUNGSTEN

In company with all other ferro-alloy metals, tungsten in 1936 continued the remarkable recovery that began in 1934. The world production in 1935 (exclusive of Spain and Argentina)—21,900 metric tons of equivalent 60-percent WO_3 concentrates—was the largest on record, except for the two peak war years 1917 and 1918, when world output was 25,797 and 31,917 metric tons, respectively. Data are not yet at hand on which to base even a rough estimate of world production for 1936, but it seems likely from the few details available that the 1936 figures will at least equal and may very well surpass those for 1935. Although production in China has increased markedly since 1934, the most striking feature in the world picture has been the phenomenal rise in exports from Burma, which during 1936 apparently exceeded those from China.

United States production, which had been ample for the meager apparent domestic consumption during the worst depression years, continued to rise, but not nearly as rapidly as did consumption. Imports therefore increased sharply.

Prices.—London prices for Chinese wolfram concentrates containing 65 percent WO_3 , as quoted by the Mining Journal (London), opened 1936 at about 35s per long-ton unit of WO_3 , c. i. f., declined steadily to a low of 25s in August, recovered to 29s in September, and finally rose to about 32s 6d in December. According to the Engineering and Mining Journal domestic scheelite quotations were steady at \$16 per short-ton unit of WO_3 in January-May, inclusive, then declined to a low of \$14 in August, after which they rose again to \$15.50–\$16 in December.

DOMESTIC PRODUCTION

Under the impetus of the favorable prices that prevailed during 1936, particularly throughout the last few months of the year, domestic tungsten mining enterprises increased the output from established producing operations and undertook considerable development work to reopen old but dormant properties. The output of tungsten concentrates in 1936 (reduced to equivalent 60 percent WO_3) amounted to 2,612 short tons compared with 2,395 tons in 1935, an increase of 9 percent. Production was reported from Arizona, California, Colorado, Idaho, Montana, New Mexico, Nevada, and Washington; of these, Nevada maintained its position as the largest producer.

Salient features of the domestic tungsten industry have been summarized by Leith and Liddell¹³ and later by Segerstrom.¹⁴

Concentrated tungsten ores (reduced to equivalent of 60 percent WO₃) produced in the United States, sold in 1927-36, and average price per unit

Year	Short tons	Value	Average price per unit	Year	Short tons	Value	Average price per unit
1927-----	1, 164	\$724, 000	\$10. 37	1932-----	396	\$218, 394	\$9. 20
1928-----	1, 208	753, 900	10. 40	1933-----	895	514, 234	9. 58
1929-----	830	654, 000	13. 13	1934-----	2, 049	1, 791, 316	14. 57
1930-----	702	509, 000	12. 09	1935-----	2, 395	1, 921, 017	13. 37
1931-----	1, 404	928, 000	11. 02	1936-----	2, 612	2, 323, 818	14. 83

Arizona.—Shipments of tungsten concentrates from Arizona operations in 1936 totaled 423 short tons averaging 69.42 percent WO₃, compared with 339 tons averaging 69.78 percent WO₃ in 1935.

By far the largest operator was the Borianna Mining Co., producing wolframite concentrates from its Borianna mine near Yucca, Mohave County. The tungsten occurrence here was recently briefed by the United States Geological Survey.¹⁵ The Southwest Ore Corporation shipped 12 tons of hübnerite concentrates averaging 63 percent WO₃ from its Las Guijas mine near Arivaca in Pima County before selling the property to the General Electric Co. The latter company did not operate the mine in 1936 after acquiring it. Hübnerite concentrates were also shipped by A. H. Yeagley from surface operations near Dagoon, Cochise County. About 17 tons of scheelite concentrates running 71.14 percent WO₃ were shipped from the Tungsten Reef mines near Hereford, operated by J. J. Seeman, and additional scheelite was shipped by Gold, Silver, & Tungsten, Inc., from the Huachuca claims in the same vicinity.

California.—Shipments of scheelite concentrates increased considerably in 1936 over 1935, output having been reported from two operations—the Atolia mine of the Atolia Mining Co. near Atolia in San Bernardino County and the tungsten-gold placer of Atolia Rand Placers, Inc., in the same vicinity. The former company is the larger producer and reported a 1936 output of 22,524 tons of ore averaging 0.8 percent WO₃, from which 186 tons of concentrates running 67.26 percent WO₃ were recovered and about 180 tons shipped. A brief description of operations in this area was given by the United States Geological Survey.¹⁶

A. E. Beauregard reported development work on his Black Rock group of scheelite claims near Bishop, Mono County, and the United States Vanadium Corporation on its Pine Creek mine near Independence.

Colorado.—Tungsten operations in Colorado center around the ferberite veins in Boulder County. The two largest operators are the Wolf Tongue Mining Co., operating a mill at Nederland, and Gold, Silver, & Tungsten, Inc., with a mill at Tungsten. Total shipments

from the State in 1936 were 256 short tons of concentrates running 42.25 percent WO_3 , compared with 519 tons running 45.06 percent WO_3 in 1935. Both of the above companies purchase ore, usually in very small lots, from as many as a hundred small operators and leasers, in addition to operating their own mines. Of the purchased material, about half is obtained by hand-sorting old dumps, simple hand jigs being used at many operations. Old tailings are also being reworked. W. L. Tanner reported 488 tons of crude ore mined from the Tanner Group; from this 29 tons of concentrates running about 66 percent WO_3 were recovered. Shipments totaled 21 tons.

Idaho.—Operations were started at the Ima mine on Patterson Creek about 11 miles east of May by the Ima Mines Corporation; 800 tons of ore were mined and milled at this operation in 1936, and about 15 tons of 65-percent WO_3 concentrates and 100 tons of sulphide concentrates containing silver, copper, and lead were recovered. Recent installation of new flotation equipment and jigs now permits a daily output of about 1,000 pounds of tungsten concentrates and 3 tons of sulphide concentrates.

Nevada.—Nevada retained its position as the largest tungsten producer in 1936, with a total output of 1,631 short tons of equivalent 60 percent WO_3 concentrates. Most of the output came from mines of the Nevada-Massachusetts Co. near Mill City, augmented by considerable production from mines of the same company at Silver Dyke near Mina. Both operations produce scheelite but are quite different geologically. The Mill City deposits are tungsten-bearing contact-metamorphosed thin limestone beds within slates, whereas the Silver Dyke deposits, recently described in detail by Kerr,¹⁷ are tungsten-bearing quartz-albite veins associated with a diorite stock that intrudes presumably Triassic volcanics and intercalated sediments. Operations at Mill City were continuous throughout the year at the present milling capacity of about 250 tons a day. A new flotation unit was added to the mill to decrease slime losses.

According to Kerr, the Silver Dyke operation consists of more than a mile of tunnels and drifts, milling capacity is about 100 tons a day, and production at the present rate should total 250 to 300 tons of scheelite concentrates a year. Capacity was recently increased by improvement in milling, which was made possible by more abundant water supplies brought in from the nearby Pilot Range.

The Rare Metals Corporation of New York completed its new milling plant at Toulon on U. S. Highway 40 and the Southern Pacific Ry. about 10 miles southwest of Lovelock, and operations presumably began late in the year. The 150-ton mill will draw ore from the recently discovered Oreana deposit operated by the same company and also from several small operations owned by other individuals in the vicinity.

Washington.—Tungsten Producers, Inc., mined 1,900 tons of ore from its Germania mine near Fruitland, Stevens County, from which 38 tons of wolframite concentrate assaying 69 percent WO_3 were recovered and shipped between April 1 and October 1. The General Electric Co. purchased the property on July 1, took over operations on October 1, and did nothing but development work for the remainder of the year.

¹⁷ Kerr, Paul F., The Tungsten Mineralization at Silver Dyke, Nev.: Univ. of Nevada Bull., vol. 30 no. 5, June 15, 1936.

Tungsten Mines, Inc., turned over control of its property about 17 miles northeast of the Germania mine to the Standard Chemical & Engineering Co. of Chicago.

IMPORTS AND EXPORTS

Domestic supplies of tungsten, which were adequate for the greatly reduced demand during the depression years 1932-33, inclusive, are insufficient for requirements during periods of normal industrial activity, so the United States imports both tungsten concentrates and products, principally the former. Imports of ore and concentrates for consumption (tungsten content) amounted to 3,586,293 pounds in 1936, more than four times the 1935 imports of 812,622 pounds. In addition, 579,027 pounds of tungsten in concentrates were imported in bond for smelting, refining, and export compared with 815,038 pounds in 1935. Imports of tungsten ore and concentrates and of tungsten metal and compounds in 1935 and 1936, by countries, are shown in the following tables:

¹ Includes combinations containing either metal or carbide.

Since 1931 the great bulk of our exports of tungsten products has consisted of shipments of ferrotungsten to the U. S. S. R. (Russia). Exports during 1936 of tungsten metal, wire, shapes, and other alloys amounted to 103,877 pounds valued at \$615,081. Exports of ferrotungsten are now grouped with ferrosilicon and ferrovanadium, so that a reasonably close estimate of total tungsten metal in various compounds and alloys exported is no longer possible.

CONSUMPTION AND USES

Apparent consumption.—Owing to the change in classification of exports containing tungsten, it is no longer possible to make a reasonably accurate estimate of apparent domestic consumption.

Uses.—The principal uses of tungsten are in the manufacture of high-speed tool steels, cemented tungsten carbides, stellites, and electric light and radio-tube filaments; in the preparation of various chemicals, such as pigments; and in the tanning of white leather. Detailed discussion of these uses may be found in previous chapters of the Minerals Yearbook. Reference is also made to the recently revised reference book covering the production, metallurgy, properties, and applications of tungsten by Smithells¹⁸ and to the chapter on tungsten by W. P. Sykes in *Modern Uses of Nonferrous Metals*, A. I. M. E. Series, 1935 (pp. 376–388). A recent development that offers promise of new outlets for the metal is the electrodeposition of tungsten with other metals in binary, ternary, and even quaternary combinations.¹⁹

WORLD PRODUCTION

Virtually all the important producing countries have shared in the increased demand for tungsten during the past 3 years.

World production of tungsten ore, 1932–36, by countries, in metric tons of concentrates containing 60 percent WO₃

¹ Data not available.

² Exports.

³ Less than 1 ton.

⁴ Exclusive of Argentina and Spain.

Argentina.—Shipments during the past 2 years have amounted annually to about 350 tons of concentrates (chiefly wolframite) assaying about 70 percent WO₃; production has come from deposits controlled by American capital.²⁰

China.—Exports officially recorded totaled 7,638 metric tons of equivalent 60-percent WO₃ concentrates in 1936 compared with 7,998 tons in 1935. The outstanding feature in the Chinese tungsten trade in 1936 was the development of a central monopoly, the Nanking Tungsten Bureau, functioning under the National Resources Commission of the Nanking Government, which apparently assumed effective control of all Chinese sources of tungsten. Other provincial monopolies, such as the Kiangsi Wolfram Mining Bureau and the Canton Monopoly, which had functioned independently during the past few years, were either abolished or made subsidiary to the central bureau. This change was effected in about midyear. Troop movements caused a brief cessation of production in southern Kiangsi late in July, but output was resumed in August. Local prices slumped severely during July–October, following rapid liquidation of stocks by the local monopoly, but with gradual depletion of speculators' stocks and effective control by the new monopoly prices gradually recovered, and at the close of the year the market was firm.

²⁰ U. S. Bureau of Mines, Mineral Trade Notes: Nov. 20, 1936, p. 16.

Hong Kong.—An important development in Hong Kong was the granting by the Hong Kong Government of a concession of some 540 acres near Needle Hill, in the New Territories, to Marsman & Co., of Manila, for the exploitation of tungsten deposits believed to exist there.

India, British.—The entire production comes from Burma, principally from the Hermingyi mine, near Tavoy, and the Mawchi mine, in the southern part of Karenni State. Exports of mixed tin and wolfram concentrates during 1936 were 8,553 metric tons, compared with 7,600 tons in 1935; most of these shipments went to the United Kingdom. Construction of a new direct motor route between the Mawchi mine and the main railway at Toungoo was completed and opened for traffic late in 1936; it is expected to permit substantial savings in transport charges. Prospecting on the company lease east of the present mine workings has revealed a large area of mineralized granite weathered so thoroughly and deeply that it can probably be worked at an extremely low cost by sluicing or other large-scale surface methods.²¹

Malay States.—Exploration work at the Kramat Pulai mine, the main source of tungsten (principally scheelite) concentrates in this area, apparently proved disappointing, since it was reported²² that the total ore located up to midyear would only suffice to keep the mill running some 21 months. Exports, almost entirely scheelite, totaled 1,395 metric tons in 1936, almost identical with 1935.

Southern Rhodesia.—Development work by St. Swithin's Ores & Metals, Ltd., on its Tshontanda wolframite operation has warranted the erection of a plant to treat 120 tons a day; construction was started late in 1936. Additional claims containing tungsten have been staked by the company along a belt over 40 miles long.²³ Production totaled 88 metric tons in 1936 compared with 26 tons in 1935.

U. S. S. R. (Russia).—Two discoveries of tungsten were reported in Kasakstan—one in the Chingis-Tow Mountains near Karkaralinsk and the other in the Akchetow Mountains about 140 kilometers north-east of the new copper works on Balkash Lake and 80 kilometers from the Turkestan-Siberian Railway.²⁴ Development work proceeded on a scheelite deposit in the Shirin-raion (Kasakstan), where a shaft was sunk and an experimental mill constructed.²⁵

VANADIUM

Recovery of the vanadium industry was in full swing in 1936, following the severe depression drop which resulted in virtually complete cessation of world output during 1933 and 1934. Production in the United States, now centering around vanadium recovery in complex ores from Arizona, in carnotites from Colorado and Utah, and in vanadium ore from Colorado and Arizona, increased considerably in 1936 but was still inadequate to meet domestic requirements. Imports from Peru therefore supplemented domestic supplies by 1,867 short tons of concentrates containing 171 short tons of vanadium in 1936 compared with 476 short tons of concentrates containing 47 tons of vanadium in 1935. Following extensive development work and installation of new milling equipment in 1936 by the

United States Vanadium Corporation at Uravan, Colo. (near the old Paradox Valley carnotite operations), and by the International Vanadium Corporation near Dripping Springs, Ariz., forthcoming production from these operations will go a long way toward making the United States self-sufficient in this important ferro-alloy mineral.

Steady operations were resumed by the Vanadium Corporation of America at its Minasragra mine in Peru and also by the South-West Africa Co., Ltd., at its Abenab mine in South-West Africa; both mines were reopened late in 1935, so that production outside the United States totaled 912 metric tons of vanadium in concentrates in 1936 compared with 416 tons in 1935.

According to verbal advice from C. Rees, vice president, Vanadium Corporation of America, some 50,000 pounds of V_2O_5 are recovered annually from boiler and stack soot of ships burning Venezuela and Mexican oil for fuel. Until recently, much of this was recovered and marketed by various contractors on the east coast of the United States who cleaned the boilers of these ships during their calls here, but apparently much of this business is now being done in Europe. The soot runs anywhere from 2 to 34 percent V_2O_5 , the richer recoveries being made by tankers operating in and near Maracaibo Lake, Venezuela. Soot from Mexican oil averages around 6 percent V_2O_5 .

Purely nominal quotations for vanadium ore were unchanged through 1936 at 27½ cents per pound of contained V_2O_5 .

² Figures not available.

³ Bureau of Mines not at liberty to publish figures.

DOMESTIC PRODUCTION

Production in the United States of vanadium contained in all types of ores from which it was recovered totaled 139,512 pounds in 1936. The Bureau is not at liberty to publish total figures for 1935.

Arizona.—Continuous operations were carried on at the properties of the Molybdenum Gold Mining Co. and the Mammoth-St. Anthony, Ltd., near Mammoth, where complex ores containing recoverable values in gold, silver, lead, molybdenum, and vanadium are treated in a flotation mill operated by the former company. Clemmer and Cooke²⁶ presented results of cooperative work between the United States Bureau of Mines, the Missouri School of Mines and Metallurgy, and the Mammoth-St. Anthony, leading to successful flotation of these complex ores.

²⁶ Clemmer, J. B., and Cooke, S. R. B., Flotation of Complex Molybdenum-Vanadium Ores from Mammoth, Ariz.: Rept. of Investigations 3333, Bureau of Mines, 1937, pp. 21-38.

Colorado and Utah.—The production of vanadium in carnotite mined in scattered localities through western Colorado and south-eastern Utah amounted to 52,695 pounds in 1936 compared with 50,776 pounds in 1935. Reports cite construction of small 25-ton mills to treat low-grade carnotites by Utah Vanadium Corporation at Cedar, Colo., and the Rare Metals, Inc., near Moab, Utah.

The United States Vanadium Corporation completed construction of a 125-ton mill and roasting plant, together with an office building and model town to house about 125 men at Uravan, Colo., and production was started late in 1936. Extensive deposits of low-grade vanadium ore left behind in the old carnotite operations in the Paradox Valley area, together with waste dumps of vanadium-bearing material, constitute an important reserve to maintain operations here for many years.

USES

The principal use of vanadium is in making special alloy steels and irons, and minor amounts are employed in the form of ammonia meta-vanadate as a catalyst in the manufacture of sulphuric acid. Further details concerning its use may be found in former reports of this series in Minerals Yearbook, in the A. I. M. E. series, Modern Uses of Nonferrous Metals (pp. 213–216), and in the pamphlet, Vancoram Ferro-Alloys, issued by the Vanadium Corporation of America in 1936.

WORLD PRODUCTION

Aside from resumption of steady operations at the Minasragra mine in Peru and the Abenab mine in South-West Africa, there are no important foreign developments to cite. Production at the latter operation was increased steadily in 1936, until late in the year it amounted to about 450 long tons of concentrates averaging 19.75 percent V_2O_5 per month, all of which is exported. World production is shown in the following table:

Activity in the bauxite and aluminum industries of the United States returned to predepression levels in 1936. Bauxite production was the largest since 1928, and the aluminum output was less than 2 percent below the peak production of 1930. Apparent consumption of bauxite and primary aluminum showed large increases over 1935 and approached all-time peaks. There was a slight decline in the average value of bauxite sold by producers, but the quoted price of aluminum was unchanged. Producers' stocks again were reduced substantially during the year.

Outside the United States, production and consumption of bauxite and aluminum in 1936 exceeded all previous records. Germany was the outstanding aluminum producer abroad, having increased its output 37 percent above that in 1935. Activity in the foreign industry was due primarily to armament and nationalistic programs, although recovery in general industrial activity and new uses also were important factors. Construction of several new plants and additions to old plants were completed or begun during 1936.

¹ Estimated.

² Revised figure.

³ New York: 1929, virgin metal 98-99 percent pure; 1935-36, 99 percent plus pure virgin ingot.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

BAUXITE PRODUCTION

Arkansas accounted for 95 percent of the total quantity of bauxite mined in the United States in 1936. Nine underground and open-pit mines near Bauxite in Saline County furnished much of Arkansas' output, and the rest came from five properties near Sweet Home, Pulaski County. Alabama and Georgia contributed the remaining 5 percent of domestic production. There were two producers in Alabama at Eufaula, Barbour County, and three in Georgia—two at Andersonville, Sumter County, and one at Kingston, Bartow County.

Bauxite of domestic origin shipped in 1932-36

Pulaski Bauxite Co., 301 Southern Building, Little Rock, Ark.—Pulaski open-pit mine, Pulaski County, Ark.

Republic Mining & Manufacturing Co., 230 Park Avenue, New York, N. Y.—Davis and Crosscut No. 23 shaft mines, open-pit mines in secs. 14, 15 (area B), and 23, and Maud Nos. 1, 2, and 3, Saline County, Ark.; Sweethome open-pit and shaft mine, Pulaski County, Ark.; and Eufaula open-pit mine, Barbour County, Ala.

Southern Minerals, Inc., 302 Standard Building, Atlanta, Ga.—A new producer at Kingston, Bartow County, Ga.

The bauxite in Saline and Pulaski Counties, Ark., is the result of superficial alteration of nepheline syenite. Bramlette's² investigation, which included the drilling of test holes and some surface mapping, shows that large quantities of nonmerchantable bauxite occur between two areas of syenite. Although a blanket of bauxite may have formed upon the syenite projecting above the contact of the Midway and Wilcox groups of the Eocene, the syenite occurring below this geological horizon is little altered and is not accompanied by bauxite. Bramlette's report gives detailed information on the occurrence of the bauxite as well as the possibility of more extensive reserves in undiscovered deposits.

² Bramlette, M. N., *Geology of the Arkansas Bauxite Region*: Arkansas Geol. Survey Inf. Circ. 8, 1936, 68 pp.

The other principal bauxite occurrences in the United States are in southeastern and northeastern Alabama and in central and northwestern Georgia. The Chattanooga district of Tennessee has not produced bauxite since 1928, and the low-grade deposits in north-central Mississippi have not been worked commercially. The alunites in Utah and other States and possibly the leucites of Wyoming must also be considered in any study of aluminum ore reserves.

CONSUMPTION BY INDUSTRIES

Bauxite is used in the manufacture of aluminum, chemicals, abrasives, cements, and refractories. The following table shows the shipments of domestic bauxite for these purposes during the past 5 years.

Domestic bauxite shipped by producers in the United States, 1932-36, by consuming industries, in long tons

Year	Alumi- num	Chem- ical	Abra- sive ¹	Ce- ment and refrac- tory ¹	Total	Year	Alumi- num	Chem- ical	Abra- sive ¹	Ce- ment and refrac- tory ¹	Total
1932----	28,899	61,838	5,612	-----	96,349	1935----	112,154	66,316	53,684	1,758	233,912

¹ Small quantity of bauxite shipped to makers of refractories probably included under Abrasive.

Aluminum.—The aluminum industry consumed 57 percent of the domestic bauxite production in 1936. All bauxite used in the manufacture of aluminum is shipped to East St. Louis; here both Arkansas and South American bauxites are refined to alumina, which is shipped to aluminum-reduction plants in carload lots. Of the aluminum produced in 1936, about half was derived from domestic bauxite and half from imported South American bauxite. Some alumina is exported to Canada and Norway for reduction purposes, and a small portion is consumed in other uses.

Although alunite, leucite, and high-alumina shales and clays have been employed to produce aluminum, bauxite at present is the only commercial ore. Japan is experiencing difficulty in producing a good-quality aluminum from alunite and Manchurian shales, and the Aurelia plant in Italy failed in its first attempt to make commercial metal from leucite. Although Germany can produce aluminum from its rich clay deposits in Saxony, the process is by no means economical. Bauxite is paramount not only for its high content of alumina but also its low content of silica. Silica is undesirable because it is soluble in the hot, alkaline solutions by means of which alumina (Al_2O_3) is extracted most easily from ores. In making alumina in the United States by the Bayer process, a silica content up to 7 percent is permitted. The typical bauxite contains 55 to 65 percent alumina, 2 to 5 percent silica, 1 to 25 percent ferric oxide, 1 to 3 percent titanium dioxide, and 10 to 30 percent combined water. United States bauxites probably average 58 percent alumina and 5 to 6 percent silica. Approximately 2 tons of bauxite are required to make 1 ton of alumina, and 2 tons of alumina are required to make 1 ton of aluminum. Cheap electrical power is necessary to reduce alumina to metallic aluminum. To make 1 ton of aluminum it is said that 24,000 kilowatt-

hours of electricity, 22,000 cubic feet of natural gas, and 9 tons of raw materials (including bauxite, coal, soda ash, limestone, fluorspar, cryolite, petroleum coke, pitch, and other materials) are required.

Chemical.—In 1936, manufacturers of aluminum salts consumed 170,561 long tons of domestic and foreign bauxite, an increase of 32 percent over 1935. The average cost of this material at consumers' plants was \$10.99 per ton. This tonnage included 20 percent of the total domestic shipments. In addition to bauxite, aluminum-salts manufacturers used 859 short tons of aluminum metal in 1936.

The following tables, which show the quantity of aluminum salts produced in recent years, do not include alumina made as a preliminary step in the manufacture of aluminum.

Aluminum salts produced in the United States, 1935-36

² Revised figures.

Aluminum sulphate, usually prepared by the digestion of bauxite in sulphuric acid, is used principally in water purification, in paper making, and as a mordant in dyeing. Aluminum chloride is used in carbonizing wool and in the refining of petroleum. The many uses of sodium-aluminum sulphate and the alums are given by Umhau.³

Activated alumina, a partly dehydrated aluminum trihydrate, is used as a commercial adsorbent in dehumidification and air conditioning, in the adsorption of gases and vapors, in the removal of water from liquids, in the adsorption of substances in true or colloidal solution, as a filtering medium, and as a catalyst or catalyst carrier. Aluminum monohydrate D ($\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$), characterized by very low bulk density and small particle size, is used in the insulation of high-temperature operations. Crude alumina, left as tailings from the World War treatment of Marysvale (Utah) alunite for its potash content, is now sold by the Mineral Products Corporation to copper smelters and refiners for use as a mold wash in casting anode bars. This production, however, is not included in the aluminum-salts statistics.

Abrasive.—The abrasive industry consumed 23 percent of the 1936 domestic production of bauxite. Some of the bauxite exported from Arkansas to Canada is used in artificial abrasives. Much of the so-called emery paper and polishing compounds and various types of grinding wheels and whetstones are made of fused bauxite.

Cement and refractory.—The cement and refractory industries consumed less than 1 percent of the bauxite produced in the United States during 1936. However, a small quantity of bauxite sold to makers of refractories is probably credited to the abrasive industry. Alumina-cement manufacturers require a bauxite with less than 2 percent silica and therefore import most of their requirements, chiefly from Europe. Bauxite brick, a high-aluminum refractory, is made from calcined bauxite in varying proportions with a bonding material of fireclay, sodium silicate, or lime. The use of bauxite in making synthetic mullite, an aluminum silicate refractory, has increased the past few years. The diasporic (high-alumina) clays produced in central Missouri supplant bauxite in the manufacture of some refractories.

FIGURE 35.—Trends in domestic and world bauxite production compared with United States imports and exports, 1913-36.

PRICES

The largest consumers of bauxite in the United States own their own deposits, and other consumers usually contract in advance for their supply of bauxite. The market for new production is small, and prices vary widely. Domestic producers reported sales of bauxite during 1936 at prices ranging from \$4.98 to \$11.56 per long ton. The average value for Arkansas bauxite was \$5.89 per ton, for Alabama and Georgia \$6.41, and for the United States \$5.91. Quoted prices for bauxite in 1936, according to Engineering and Mining Journal Metal and Mineral Markets, were as follows: Domestic—chemical ore, crushed and dried, 55 to 58 percent Al_2O_3 and 1.5 to 2.5 percent Fe_2O_3 , \$6 to \$7.50 a long ton f. o. b. Alabama and Arkansas mines; foreign—Dalmatian, 50 to 55 percent Al_2O_3 and 1 to 3 percent SiO_2 , \$4.50 to \$6 per metric ton c. i. f. Atlantic ports; Istrian, 54 to 57 percent Al_2O_3 and 3 to 5 percent SiO_2 , \$5.50 to \$6; and French, 56 to 59 percent Al_2O_3 and 2 to 4 percent SiO_2 , \$5.50 to \$6.50.

FOREIGN TRADE

Bauxite imports in 1936 increased 61 percent while exports gained only 2 percent compared with 1935. The 1936 imports originated as follows: Surinam, 217,359 long tons; British Guiana, 91,193; Yugoslavia, 7,150; France, 6,985; and British India, 103.

Bauxite exports do not represent a true comparison to bauxite imports because they consist chiefly of calcined bauxite and alumina instead of crude ore. Of the 1936 exports classified as bauxite and other aluminum ores (56,227 long tons total), 56,226 tons went to Canada and 1 ton to Trinidad and Tobago; exports classified as bauxite concentrates, including alumina (28,244 long tons total), were consigned as follows: Canada, 19,681 long tons; Norway, 4,117; Italy, 3,739; Sweden, 704; and China, 3.

The total supply of bauxite, domestic production plus excess of imports over exports, totaled 610,324 long tons compared with 351,380 tons in 1935.

Bauxite imported into and exported from the United States, 1932-36

Year	Imports for consumption		Exports (including bauxite concentrates)		Year	Imports for consumption		Exports (including bauxite concentrates)

ALUMINUM

PRODUCTION

New aluminum produced in the United States during 1936 increased 89 percent in quantity and value over 1935. Secondary aluminum output amounted to 103,000,000 pounds in 1936, only a slight increase over 1935, according to J. P. Dunlop of the Bureau of Mines. The production of secondary aluminum was equivalent to 46 percent of

the primary output in 1936. Of the primary aluminum produced in 1936, 41 percent was made at Massena, N. Y.; 30 percent at Alcoa, Tenn.; 19 percent at Badin, N. C.; and 10 percent at Niagara Falls, N. Y. The aluminum-reduction plant at Niagara Falls, closed since July 1931, resumed operations in January 1936.

² Revised figures.

FIGURE 39.—Domestic and world primary aluminum production compared with domestic imports and exports of crude and semicrude, apparent consumption, secondary production, and average New York quoted price, 1913-36. Price is No. 1 virgin 98-99 percent through 1929, thereafter 99 percent plus virgin ingot, as reported by American Metal Market.

CONSUMPTION

The following table shows apparent consumption of primary aluminum in the United States from 1929 to 1936, inclusive. As the table does not consider fluctuations in producers' and consumers' stocks, it does not show actual consumption for any given year. During the first years of the depression there was a considerable accumulation of stocks at producers' plants. During the past 3 years withdrawals from these stocks have been as follows: 1934, 26,079 short tons; 1935, 27,515 tons; and 1936, 13,279 tons. The addition of these tonnages to the apparent consumption shown in the table would more accu-

rately reflect actual consumption of primary aluminum during 1934, 1935, and 1936.

Virtually all secondary metal is consumed as soon as it is gathered in the scrap market. From 1929 to 1936 secondary aluminum production was equivalent to 48 percent of the apparent consumption of primary metal.

Aluminum available for consumption in the United States, 1929-36, in short tons

	1929	1930	1931	1932	1933	1934	1935	1936

¹ Revised figures.

² Crude and semicrude, some of which may be secondary aluminum.

Increased consumption of aluminum in 1936 was due to the general improvement in industrial activity, which increased demand in well-established uses, as well as to new uses which have been developed, particularly in products where strength is a controlling factor. Among the latter was the use of aluminum in the construction of an emergency bulkhead for a roller-gate dam at Gallipolis, Ohio, where seven 28-ton units were installed. The metal was also used in construction of bulkheads for windows at a Pittsburgh store to serve as a protection against flood waters. Following the completion of the record-size 32-cubic-yard shovel dipper over a year ago, aluminum has been used in other excavating and loading equipment. Substitution of aluminum in cargo buckets has permitted 60 loads to be made per hour from the hold of a steamer in place of 40 with old-style equipment. A 25,000-pound aluminum grab bucket was developed at Duluth because of its resistance to corrosion from sulphur in the sulphur-bearing coal. The first aluminum dredge-boom, the longest ever made in any metal, was placed in service during the past year. Its total length is 240 feet; of this the inner 90 feet is steel and the outer 150 feet aluminum. Because the outer end of the boom is so much lighter, a 6-cubic-yard bucket was substituted for one with 4-cubic-yard capacity.

An aluminum bridge-floor system was installed on the Stratford Avenue Bridge in Bridgeport, Conn. The new marsh buggy for travel on land or water, used to prospect oil regions in swamps and bayous, is built of this light metal. The brewing industry is now using aluminum tanks for fermentation and storage. Aluminum beer barrels are lighter than wood, have a larger capacity, and can be stored in less space; the ordinary container weighs 70 pounds empty and holds 13 gallons, while an aluminum barrel weighs 18 pounds and holds 15½ gallons. Aluminum bottle caps and seals, are employed in great quantities.

The use of aluminum paint as a protective coating has doubled since 1929. Three of the largest bridges, besides hundreds of smaller ones, were painted with aluminum paint during the past year. The three large bridges were: Tri-Borough and George Washington,

New York; and the San Francisco-Oakland Bay Bridge, California. The latter used more than 50,000 gallons of aluminum paint as the final coat. Aluminum foil was used as insulation in refrigerator cars and trucks in 1936. A few of the many other newer uses of aluminum include lighting reflectors, license plates, windows for home construction, and a new pigment for lithographing packages.

PRICES

According to the American Metal Market the average price for 99-percent-plus pure virgin ingot aluminum, delivered, based on open market quotations in New York, remained at 20.50 cents a pound throughout 1936. Quotations ranged from 19 to 22 cents, with no explanation of the 3-cent spread. On March 1, 1937, the quotation was changed to 20 cents for carload lots with $\frac{1}{2}$ cent premium for smaller lots down to 1 ton, and a 1-cent premium for less than ton lots. The increase of 1 cent on minimum quotations was attributed to increased costs of production.

FOREIGN TRADE

Foreign trade in unmanufactured aluminum in 1936 showed a substantial increase in imports and a sharp decline in exports. The quantity of crude and semicrude metal imported in 1936 was 20 percent more than in 1935, whereas exports declined 60 percent. Net imports of crude and semicrude aluminum accounted for 10 percent of the apparent consumption of primary metal in 1936. Imports of aluminum manufactures increased 74 percent in value, and exports declined 11 percent.

Aluminum imported for consumption in the United States, 1934-36, by classes

Class	1934		1935		1936

TECHNOLOGIC DEVELOPMENTS

Only minor improvements were made in the metallurgy of aluminum in the United States in 1936. In Europe a saving in cost of \$4 or more per ton of alumina is said to have been accomplished by substitution of continuous-pressure apparatus for decomposing bauxite with alkali in place of the intermittent autoclave method now used in the Bayer process.⁴

The production of aluminum sheet, down to 0.120 inch in thickness, by direct rolling from molten aluminum has been announced by the Crown Cork & Seal Co., of Baltimore, by use of the Hazlett mill.⁵ The sheets will be annealed and rolled to produce aluminum foil for use as "spots" in the crown cork. Direct-rolled molten steel is also to be developed. The company is also producing hot-dip aluminum-coated steel sheet for making crown tops and various containers, which is said to be superior to tin plate.

Many technologic advances have been made in treating aluminum against corrosion. One of the principal methods is the application of a resistant oxide coating. The Alumilite and Alzak anodizing processes for oxide coatings are used chiefly in this country.

Improvements in welding aluminum and its alloys have been recorded by Hoglund.⁶

Several recent articles⁷ describe progress in the manufacture of aluminum alloys.

The United States Bureau of Mines is studying the problem of recovering potash and alumina from the alunites of the West, principally in Utah and within short distances from Boulder Dam. The study,

WORLD BAUXITE AND ALUMINUM INDUSTRIES

BAUXITE PRODUCTION

The estimated 1936 world production of bauxite is 2,600,000 metric tons compared with 1,744,000 tons in 1935, an increase of nearly 50 percent. This large increase in output resulted from the comparatively new production in Netherland India and increased activity in all countries, notably Hungary, Yugoslavia, France, United States, British Guiana, Surinam, Italy, and Greece. France contributed 29 percent of the 1935 bauxite output, United States 14 percent, Yugoslavia and Hungary each 12 percent, Italy 10 percent, U. S. S. R. (Russia) 8 percent, and British Guiana and Surinam each 6 percent.

ALUMINUM PRODUCTION

The world output of aluminum in 1936 was approximately 357,600 metric tons compared with 259,300 tons in 1935, an increase of 38 percent. The United States produced 29 percent of the 1936 total, Germany 27 percent, U. S. S. R. (Russia) 8 percent, Canada 8 percent, France 7 percent, United Kingdom 6 percent, Italy 5 percent, and Switzerland and Norway each 4 percent. The United States and Germany showed the largest increases in tonnage.

¹ Data not available. Estimate included in total.

ALUMINUM CONSUMPTION

World consumption of aluminum in 1935, the latest year for which figures are available, has been estimated by Metallgesellschaft at 307,000 metric tons. The principal consumers and the percentage of the total each accounted for were: United States, 28.5; Germany, 28.3; United Kingdom, 9.3; U. S. S. R. (Russia), 8.1; France, 7.8; Italy, 4.9; Japan, 4.1; Switzerland, 2.3; and Canada, 1.7. Europe accounted for 64.7 percent of the total world consumption.

REVIEW BY COUNTRIES

Australia.—The British Aluminium (Australia) Proprietary, Ltd., was recently formed to produce aluminum, with Risdon, Tasmania, rumored as the site for the works. The source of bauxite supply has not been determined, but small deposits occur in the Gippsland district of Victoria; in the Emmaville, Wingello, and Inverell districts of New South Wales; and in Queensland.

Brazil.—Bauxite occurs in Minas Geraes, São Paulo, Espírito Santo, Goyaz, Bahia, and the Para River district, Brazil. Exports of bauxite in 1936 were 7,000 metric tons. Of this quantity, the Companhia Geral de Minas shipped 4,000 tons from its deposits near Pocos de Caldas in Minas Geraes and São Paulo to Argentina for the production of aluminum sulphate. Ore from this vicinity runs about 60 percent Al_2O_3 , 2 percent SiO_2 , and 4 percent Fe_2O_3 . Bauxite at Saramenha, near Ouro Preto, Minas Geraes, is under exploitation by the Companhia Electro-Chimica Brasileira.

British Guiana.—Much of the ore mined by Demerara Bauxite Co., Ltd., in British Guiana is now shipped directly to the new Arvida alumina plant of the Aluminum Co. of Canada, Ltd., whereas most of it formerly was processed at East St. Louis.⁹

Canada.—Bauxite imports into Canada increased from 115,490 metric tons in 1935 to 155,506 in 1936. Shipments from the United States and the United Kingdom consist largely of calcined bauxite and alumina.

⁹ Harder, E. C., *British Guiana and Its Bauxite Resources*: Canadian Inst. Min. and Met., 1936, pp. 739-758.

The increase in bauxite imports is due chiefly to the fact that the Aluminum Co. of Canada, Ltd., a subsidiary of Aluminium, Ltd., began to convert British Guiana crude bauxite into alumina by the Bayer process at its Arvida plant in March 1936. Until the erection of this new alumina plant, most of the alumina was imported from the United States. Aluminum-reduction works using the Hall process are located at Arvida and Shawinigan Falls. The Shawinigan Falls reduction plant had been shut down but resumed operations in August 1936. The metal is fabricated at the company plants in Toronto and Shawinigan Falls.

France.—The large bauxite deposits of France are operated by French, Swiss, and British interests. The Cie de Produits Chimiques et Electrometallurgiques Alais, Froges et Camargue (Péchiney) operates three alumina and eight aluminum-reduction plants in the Alps and in the Pyrenees, while the Sté. d'Electrochimie, d'Electrometallurgie et des Aciéries Electriques d'Ugine owns one alumina and three aluminum-reduction works. The sales organization for both companies is the Sté. L'Aluminium Français. Construction of a new aluminum works is reported at Pond-de-Lescun, Basses-Pyrenees, by a subsidiary of the Société des Forces Motrices du Bern.¹⁰

A new process for the electrolytic refining of aluminum was put into operation by Péchiney at the St. Jean de Maurienne plant. The electrolyte, with a fusion point below 750° C., consists of 23 percent aluminum fluoride, 17 percent sodium fluoride, and 60 percent barium chloride and is claimed to reduce refractory costs and produce a metal with superior electrical conductivity and corrosion resistance.¹¹

Exportation of bauxite, alumina, or aluminum from France is controlled by a Government licensing system.

Germany.—The aluminum industry of Germany imports its bauxite; and in 1936 imports totaled 981,162 metric tons, derived principally from Hungary, Yugoslavia, Italy, and Netherland India. The German-controlled Bauxite Trust A. G. (Zurich) operates mines in Hungary, Yugoslavia, Italy, and Rumania and thus guarantees a supply from these sources.

In 1936 Germany's aluminum production was exceeded only by that of the United States. The German aluminum producers are: The State-owned Vereinigte Aluminiumwerke A. G., with plants at Hoyerswerda, Grevenbroich, and Töging, Aluminiumwerke G. m. b. H. at Bitterfeld in Sachsen, and the Swiss-owned L'Aluminium-Industrie A. G. (A. I. A. G.) at Rheinfelden in Baden. The Vereinigte Aluminiumwerke is to build a new alumina works at Schwandorf, Bavaria, and the A. I. A. G. has doubled alumina production at its Martinswerk plant. Coal-steam power supplies current for all the reduction works except the Töging and Rheinfelden plants, which use hydroelectric power.

Germany's spectacular rise in aluminum production and consumption is due to the rearmament program, with its demand for aircraft, automotive vehicles, and ships; its substitution of aluminum for other metals in order to become self-sufficient; and the effort to improve its foreign-trade balance by exports of aluminum goods.

Imports of the crude metal declined from 15,247 metric tons in 1935 to 4,258 in 1936, but exports of semimanufactured and manufactured goods, especially aluminum foil, increased. A new German-

¹⁰ Bureau of Foreign and Domestic Commerce, Foreign Metals and Minerals: Circ. 11, Jan. 29, 1937, p. 14.

¹¹ Queensland Government Mining Journal, vol. 37, no. 438, November, 1936, p. 378.

Scandinavian agreement permits Germany to export finished aluminum wares to Norway, Sweden, and Denmark as hitherto but does not allow her to increase sales in this market. The German industry wins the right to export unlimited quantities of raw and semifinished aluminum, but the Scandinavian industry reserves the expanding aluminum-ware market.

Gold Coast Colony.—Some of the largest and richest bauxite deposits lie along the equatorial belt of West Africa, although Africa has not as yet produced any bauxite. Anderson estimates a reserve of 180 million tons of good bauxite in the Yenahin district, about 45 miles west of Kumasi.¹² Some of the rich deposits at Mount Supirri in the Affoh group near Sefwai-Bekwai carry gold and silver in and beneath the laterite capping.¹³ Other Gold Coast deposits are at Mount Ejuanema near Nkawkaw, Kwahu, and at Nsisreso, Asempantaiye, N. W. Sefwi. The ore ranges from 49 to 55 percent Al_2O_3 , 0.2 to 2 percent SiO_2 , and 13 to 25 percent Fe_2O_3 .

Other Africa.—Other large bauxite deposits are found in Africa on the Lichenya Plateau in Nyasaland and in the Atlas Mountains of French Morocco, while deposits are reported in French Guinea, Sierra Leone, Tanganyika Territory, Madagascar, and Abyssinia.

Greece.—Although bauxite shipments totaled only 13,150 metric tons in 1935, the completion of mining and shipping improvements in Greece will permit an annual exportation of over 100,000 tons. The two principal producers are the Bauxites-Parnasse S. A., operating on the mainland of the north shore of the Gulf of Corinth, between Messolohgui and Thebes, and the Bauxites S. Papassotiriou, working a deposit on the Island of Amorgos adjacent to the Ægean Sea. Bauxite from the Itsea area runs about 60 percent Al_2O_3 , 3 percent TiO_2 , 2 percent SiO_2 , and 22 percent Fe_2O_3 . Open-pit mining and the proximity of some of the mines to navigable water enable operators to deliver crude bauxite at the docks for \$1.03 to \$1.60 per long ton. The 1936 exports were chiefly to Germany, United Kingdom, Japan, and Norway.

Hungary.—Most of the bauxite output comes from the Gánt deposits in western Hungary. Work has started on a new bauxite discovery in the Nagyarsány Mountains, Baranya County, southern Hungary. Although much of the bauxite is exported, particularly to Germany, Hungary has its own aluminum industry capable of supplying domestic consumption. Bauxite Industry, Ltd. (Budapest), produces alumina at Magyaróvár (Altenburg), and the aluminum-reduction works of the Aluminiumwerke Manfred Weiss A. G. (Budapest) is located at Csepel. Aluminum output is to be increased and aluminum cables and wires are to be produced.

India (British).—A recent publication describes the possibility of producing aluminum in Bombay, India.¹⁴ Most of the small output heretofore has come from the Jabalpur district, Central Provinces, and the Khaira District.

Italy.—The Istria district produces most of Italy's bauxite output. A new deposit was discovered recently in the Aidussina district near Gorizia. Large deposits of leucite, as well as some aluminite, occur in the old volcanic regions of central Italy.

¹² Anderson, Robert J., *World Resources of Aluminum Ore*: Mining Mag. (London), vol. 55, no. 6, December 1936, pp. 329-341.

¹³ Cooper, W. G. G., *Gold Coast Bauxite*: Bull. Imperial Inst., vol. 34, no. 3, July-September 1936, pp. 331-347; *Gold Coast Geol. Survey*, Bull. 7, 1936.

¹⁴ Patel, M. S., *Possibility of Production of Aluminium in Bombay*: Dept. of Industries, Bombay, Bull. 10, 1936, 27 pp.

In 1936 the Italian aluminum industry built additional plants and enlarged others. The Montecatini group controls the new alumina plant using the Bayer process and another using the Haglund process at Porto Marghera, and two aluminum-reduction works, one at Mori, which is being enlarged, and a new one at Bolzano. The Swiss-owned Società Anonima Veneta Alluminio owns an alumina plant at Bussi, and a new one is under construction at Porto Marghera. Its aluminum-reduction works at Porto Marghera, which has accounted for about half of the Italian output, is to be enlarged and an aluminum powder plant added. The Canadian-controlled Borgofranco d'Ivrea reduction works plans to increase its present annual capacity of 1,500 tons. Upon completion of all new construction, Italy's production capacity will be 60,000 tons of alumina and 30,000 tons of aluminum. This expansion will permit Italy to enlarge its aluminum exports, although a Government licensing system controls the exportation of bauxite and aluminum and its alloys.

Japan.—Bauxite is not found in Japan but is imported principally from Netherland India and Greece. Attempts are being made to produce alumina from Manchurian shale and Korean alunite, but some producers have not found this domestic raw material satisfactory and are now using imported bauxite.

Long dependent on foreign sources for aluminum, chiefly from Canada, Norway, Switzerland, and France, Japan began to develop its own aluminum industry in 1933. Aluminum works, some of which are still in the experimental stage and others which are proposed, include: The Japan Electric Industry Co.; Japan Aluminium Co. at Takao, Formosa; Nichiman Aluminium Co., also called the Japan-Manchoukuo Aluminium Co.; Aluminium Manufacturing Co., a subsidiary of the South Manchuria Railway Co., with a plant proposed in the coal fields at Fushun; Sumitomo Metal Industry Co. at Osaka; and the Korean Nitrogen Fertilizer Co. at Tumen, Manchuria.

Much of the domestic product has been considered of poor quality, due principally to the use of alunite instead of bauxite for raw material. To protect the domestic industry, an increase in the tariff on imported aluminum became effective in June 1936.

Netherlands.—A proposed aluminum works to be built in the vicinity of the Limburg coal field would utilize bauxite from the mines on the island of Bintang, Netherland India.

Netherland India.—The islands of Bintang and Batam in the Dutch East Indies are becoming large producers of bauxite. Production increased to considerably more than 100,000 tons in 1936, compared with 9,923 tons in 1935. Exports are chiefly to Germany, Netherlands, and Japan. Exploitation is by the Nederlandsch-Indische Bauxiet Exploitatie Maatschappij (subsidiary of the Billiton Tin Co.). The deposits are about 12 feet thick, and the ore contains approximately 53 percent Al_2O_3 , 2.5 percent SiO_2 , 13.5 percent Fe_2O_3 , and 1.2 percent TiO_2 .

Norway.—Aluminum-reduction plants owned by British, Canadian, and French aluminum interests are located at Eydehavn, Stangfjord, Vigeland, Tyssedal, Glomfjord, and Høyanger, Norway. The Norsk Aluminium Co. at Høyanger, owned jointly by Norwegian interests and Aluminium, Ltd., is the only concern with a plant to refine bauxite into alumina. It uses the Pedersen process and produces about 14,000 tons of alumina and 4,000 tons of crude iron annually as a

byproduct. The other plants import their alumina and export the metal produced.

In 1936 imports of bauxite totaled 24,046 metric tons (32,570 in 1935) and of alumina 23,019 tons (19,455 in 1935). Norwegian exports of crude aluminum aggregated 15,087 tons in 1936, much of which went to the United States and Germany.

Rumania.—Rumania contains large bauxite deposits in the Bihar Mountains which are exploited by the Aurum Mining Co. Erection of an aluminum works at Targoviste is under consideration.

Surinam (Dutch Guiana).—Virtually all the bauxite produced by the Surinaamsche Bauxite Maatschappij, a subsidiary of the Aluminum Co. of America, at Moengo is shipped to East St. Louis for refining into alumina. The deposits are 10 to 18 feet thick and contain about 59 percent alumina, 2 percent silica, and 6 percent ferric oxide.

The Dutch Guiana and British Guiana bauxite deposits, which occur along a belt more or less parallel to the coast, are said to extend into French Guiana and Brazil and also into Venezuela.

Switzerland.—The oldest aluminum-producing company in Europe, founded in 1889, is L'Aluminium Industrie-Aktien-Gesellschaft (A. I. A. G. or Neuhausen Co.). Its Swiss reduction plants are at Neuhausen, Canton Schaffhausen, and Chippis, Canton Valais. Raw materials are supplied by affiliated mines and plants in France, Germany, Italy, and Rumania. Affiliated aluminum-production works are at Rheinfelden, Germany; Bussi and Porto Marghera, Italy; and Lend, Austria. The Fabrique d'Aluminium Martigny, S. A., with 1,260 tons annual production, is an independent producer at Martigny-Bourg, Canton Valais. The A. I. A. G. is one of the chief promoters of the world aluminum cartel, the Alliance Aluminium Cie. (Basel), with which most of the leading world aluminum producers, except the United States, are associated.

United Kingdom.—The British Aluminium Co., Ltd., and the Aluminium Corporation, Ltd., together produce the aluminum output of the United Kingdom. Large quantities of aluminum and aluminum alloys are imported from Canada (15,423 metric tons in 1935 and 16,925 tons in 1936) and smaller amounts from Switzerland and Norway.

U. S. S. R. (Russia).—Bauxite deposits occur in the Leningrad district near Tikhvin, northwestern U. S. S. R., in the Sverdlovsk and Chelyabinsk districts of the Ural Mountains, and in the undeveloped Belovo region in western Siberia. The Ural deposits are larger and of better grade (36 to 50 percent alumina and 3.7 to 5.3 percent silica) than those at Tikhvin (44 percent alumina and 12 to 15 percent silica). Other possible raw material sources are nepheline from Karelia (Kola Peninsula) and leucite from Armenia.

Alumina works include the plants at Volkhov (Svanka), Tikhvin, and Neproges (Dnepr or Zaporozhe plant), while another is under construction at Kamensk and still another is contemplated at Kandalaksha in Karelia for the treatment of nepheline. There is an experimental alumina plant at Korov-Abad, near Tbilisi (Tiflis). Aluminum-reduction plants include the Svanka and Dnepr, with the Kamensk nearing completion and construction reported to commence shortly on another in Karelia and later in Perm. Crude artificial cryolite is to be made at the Polevskoi plant in the Urals from fluorspar obtained from the Chita region of Eastern Siberia.

The Russian aluminum industry is due to the Government self-sufficiency program and not to economic raw-material resources. Much difficulty was experienced by the Aluminium Research Institute in working out complicated processes to produce alumina from the bauxite, which is low in alumina and high in silica. The long hauls of raw materials are being alleviated by the erection of alumina and reduction plants near the mines, but shipments of materials over long distances will still be necessary to the Dnepr plant in the Ukraine.

Yugoslavia.—Economic grades of bauxite occur at many places in Yugoslavia; but most of the output, largely exported, comes from the Drnis and Sinj districts of Dalmatia and from the Knez Polje and Ygrovac districts near Mostar in Herzegovina. Aluminium A. G. (Belgrade) has commenced construction of an aluminum works at Jaruga near Sibenik which will have an annual capacity of 1,000 tons of aluminum.

The mercury industry in the United States in 1936 was characterized by a notable increase in demand, partly caused by fears concerning future supply; by lower domestic production in the face of a moderate rise in price that became substantial in the late months of the year; and by a sharp upswing in receipts of metal from foreign countries.

The continuation of civil strife in Spain, where the principal mercury reserves of the world are situated, together with increased demand for the metal in large mercury-consuming countries of Europe that are engaged in record-breaking armament preparations, continued to contribute to the tense international situation. The termination of the war between Italy and Ethiopia and the removal of sanctions against Italy, second in importance as a source of mercury, eased the situation somewhat, but it is extremely doubtful that Italy could supply the world demand for mercury even temporarily, should supplies from Spain be cut off entirely. Despite fears that Spanish production would cease, however, large quantities of metal are reported to have left that country late in 1936. The Government controlled the mines as the year ended, but some shipments were reported to have been intercepted by opposing troops.

Another event of utmost importance in the international mercury situation was the sudden breaking up of the cartel agreement between Spain and Italy. In forecasting this occurrence the Metal Bulletin of London¹ said:

The Spanish civil war has also been directly responsible for another event of the greatest importance to the quicksilver market, namely the denunciation by the Almaden mines, presumably under Government pressure, of the Cartel agreement with Italy as a protest against alleged Italian deliveries of arms to the insurgents.

The dissolution of the mercury cartel would seem to herald a renewal in the not distant future of the keen competitive conditions that prevailed prior to its formation and lower prices for the metal, barring the destruction of the Almaden mine workings and reduction equipment or a lengthy extension of the civil war in Spain.

¹ Metal Bulletin, The Quicksilver Situation: No. 2133, Oct. 20, 1936, p. 8.

In the United States the maritime strike on the Pacific coast and unusually bad weather in the final quarter of 1936 contributed to the lack of supplies of domestic mercury at the end of the year in New York. In addition, larger amounts of metal were required for placer-gold operations in Western States, thus lowering the amount of mercury available for shipment. Some metal was reported shipped east by rail in the last months of the year.

Imports of mercury in 1936 were considerably more than twice those received in 1935, and more than one-half of the quantity imported entered the country in the last quarter of the year. Increased imports, together with a relatively small decline in domestic production, indicated that larger quantities of metal were available for consumption. Greater consumptive demand only partly explains the increased importation of metal during the year, however, as fears concerning future supplies are believed to have had an important bearing on the size of purchases. The international conditions already mentioned led importers to increase their purchases of Italian metal. More than one-half of the imports from Spain arrived in the first 6 months of 1936 whereas imports from Italy increased sharply as the year progressed, those in December alone being 41 percent higher than the quantity imported in the entire first 6 months of the year.

Prices.—The average quoted price for mercury in New York was relatively stationary at approximately \$77 a flask for the first 4 months of the year. The monthly average dropped in May and continued downward until the low average of the year, \$73.42 a flask, was reached in July. Declining receipts of metal from Spain and Italy in the third quarter of the year caused a sharp upswing in prices in September, which continued throughout the final quarter of the year. Whereas the highest monthly average for the year was \$90.25 for November and December, little metal was available for sale, and trade reports were that \$95 or more would be required to buy metal in any quantity. There were appreciable differences between the prices quoted in London by the cartel agents and those asked by independent merchants, although such discrepancies continued for only a short time. According to the Metal Bulletin, September 8, 1936, Roura & Forgas, the cartel agents at that time, stated that the Almaden mines had large stocks at Alicante and also at the mines. A large shipment was expected from Spain toward the end of September, against which the agents were selling at £12 17s. to £12 17s. 6d. (\$64.72 to \$64.84) a flask. London merchants at the

same time were selling from their stocks at £20 to £22 (\$100.73 to \$110.80) per flask.

¹ Engineering and Mining Journal, New York.

² Mining Journal (London) prices in terms of pounds sterling converted to American money by using average rates of exchange recorded by the Federal Reserve Board.

Increased activity was evident at domestic mines in the latter part of 1936 as a result of the advance in price. Due to the time required to bring even a fully equipped idle mine into production, however, no increase in output was noted in 1936; in fact, production actually fell off somewhat. Should prices continue at their present levels some increase may be looked for in the near future.

Production at price.—A study of the record of production of domestic mines from 1910 to the present time brings out two facts clearly—increasingly higher prices are required to bring out a given production of mercury, and increased output is supplied by ores of diminishing grades.

In making this study, mercury index prices were used instead of actual quoted prices to reduce to a minimum the factors that would tend to distort the conclusions drawn. The mercury index price was obtained by dividing the quoted price by the Department of Labor wholesale price index for all commodities (1913=100). For the period 1910-26 quoted prices for 75-pound flasks were reduced to the equivalents for 76-pound flasks.

During the period covered by the table, demands for mercury fluctuated widely and prices moved similarly. When prices were high, larger proportions of the country's needs were supplied by metal of domestic origin. As the index price returned to a previous level, however, less metal was produced than the output when the index formerly stood at the same level. Higher prices were necessary to bring forth an output similar to former records. There were minor disturbances of this trend due (1) to the exploitation of relatively small new deposits where higher-grade ores could be treated for a time at lower cost or (2) to the discovery of richer veins in properties already productive, but these only temporarily interrupted the major trend.

Index prices for mercury ranged from \$40 to \$51 from 1910 to 1914, and production from 16,330 to 24,734 flasks. Rapidly increasing

prices in 1915 and 1916 culminated in the highest index price for the period under discussion—\$103.80 in 1916—which resulted in the peak output of 35,683 flasks in 1917. In the years 1922–25 the index price ranged from \$43 to \$57, but the resultant outputs varied from only 6,291 to 9,952 flasks. Increases that carried the price to \$89 to \$93 in 1928 to 1930 were sufficient only to bring out the recent high output of 24,947 flasks in 1931, about equal to the output of 1912 when the index stood at \$43.

As the price increased and higher outputs were made the grade of ore declined. From 1913 to 1915 an annual average of 19,011 flasks of mercury was produced from ore with a recovered mercury content of 0.52 percent. In the years 1916–18, when the peak output in the period under discussion was made, the annual average production was 32,557 flasks, but was won from ores having a recovered tenor of only 0.39 percent. The average annual output from 1921 to 1927, when output was low, was 8,293 flasks, and the average recovered tenor of ore increased to 0.51 percent. The sharply higher production of 1928–31, an annual average of 22,013 flasks, came from ores containing only about 0.31 percent mercury.

Comparing the 7 years ended in 1936 with the two preceding 10-year periods, it is found that the average annual output of 24,188 flasks produced in 1910–19 was obtained from ores with a recovered mercury content of 0.47 percent, 11,282 flasks for 1920–29 from ores averaging 0.42 percent, and 16,903 flasks for 1930–36 from ores averaging 0.35 percent. In recent years virtually all dump material and earth from under old reduction plants have been excluded in calculating tenor of ores, but fairly substantial quantities were included in some of the years prior to 1920. This situation tends to accentuate the trends indicated above.

The average annual domestic consumption of mercury is probably 25,000 flasks or more. The index price of \$93 a flask in 1930 resulted in an output of nearly 25,000 flasks in 1931, and nearly 72,000 flasks have been produced since 1931. From the preceding discussion it is clear that depletion of reserves results in smaller outputs as each price cycle returns to a previous level. A conclusion that might be drawn from this study is that an index price well above \$93 a flask (equivalent at the December 1936 average for all commodities to an actual price of \$112) would be needed to produce the desired amount for even 1 year. This price would apparently have to be raised at an accelerated rate to continue to draw the needed amount from domestic mines for even a limited period of time.

It is significant that the output of 24,734 flasks of mercury in 1912 was made by 20 mines, whereas that of 24,947 flasks in 1931 was made by 77 mines. In 1912 the two mines that have produced the largest quantities of mercury in the United States to date, the famous New Almaden and New Idria mines, and two other large properties, the Guadalupe mine, Santa Clara County, Calif., and Mercury mine, Nye County, Nev., contributed nearly 21,000 flasks to the total for the country. In 1931 these mines were either closed down or producing at a greatly reduced rate. No new mines have been discovered since 1912 with sufficient ore reserves to compensate for the loss of output from these properties. Consequently, it required a larger number of small properties in 1931 to produce—even at higher prices—as much mercury as in 1912.

¹ Prior to 1920 total tonnage treated (partly estimated), including material from old dumps, earth from beneath old reduction plants, etc., was used in calculating recovered tenor. From 1920 on old dump materials, etc., has been excluded, insofar as possible, and tenor calculated on all available data covering new ore treated. From 82 to 98 percent of the total mercury production was covered in calculating tenor for 1920-36.

² The mercury index price has been calculated for each year by dividing the New York quoted price of mercury by the Bureau of Labor Statistics wholesale price index for all commodities (1913=100).

³ Quoted prices for 75-pound flasks calculated to the equivalents for 76-pound flasks.

As a result of frequent requests received by the United States Bureau of Mines for information on the treatment of mercury ores the Metallurgical Division has prepared a report entitled *Occurrence and Treatment of Mercury Ore at Small Mines*. The main theme of this report is treatment by furnacing, but concentration, mining of the ore, and precautions against mercury poisoning are covered. Copies of this report will be available later from the Publications Section, United States Bureau of Mines, Interior Building, Washington, D. C.

Consumption and uses.—During 1936 ² the General Electric Co. installed a mercury boiler, a 1,000-kilowatt mercury turbine, a condenser-boiler making 12,500 pounds of steam per hour at 185 pounds pressure, and a 900-kilowatt steam turbine in each of its shops at Pittsfield and Lynn, Mass. These boilers require 6 pounds of mercury per kilowatt of capacity, less than is needed for the boilers at Schenectady, N. Y., and Kearney, N. J. Design sketches for a mercury-steam installation of 44,000-kilowatt capacity employing a single drum have been made by General Electric.

Continued experimentation with small mercury lights in 1936 was reported to have brought satisfactory results. Development of 85- and 100-watt bulbs, of smaller size but giving as much light as the standard filament 200-watt lamp, was reported. A small mercury-

² Power Plant Engineering, Mercury in Small Boilers: April 1937, p. 213.

break switch, silent in operation and without moving parts, was announced by the General Electric Co. and described as follows:³

The switch consists of two shallow chrome-steel cups, $\frac{3}{4}$ -in. diameter, sealed together with a strip of lead glass to form a hollow compartment. Separating the cups is a disk of ceramic material having a small hole located near the edge. After assembly, this compartment is evacuated and four grams of mercury are inserted. This fills approximately one-quarter of the space. The compartment is then filled with hydrogen at about atmospheric pressure and sealed off by welding.

In the "off" position, the hole in the ceramic disk is above the mercury line. At rotation of 20 deg. the switch assumes a position which permits mercury to flow through the hole, thus establishing contact between the two chrome-steel cups, closing the circuit.

Hydrogen serves as a cooling agent and in quenching the arc. Heating is also controlled through a mercury-to-metal contact employing a mil of platinum on a tiny plate of steel, welded on the inside of each cup.

Prospects for increased consumption of mercury in new uses were summarized as follows:⁴

While counting heavily on the demand created by long-established uses, producers are watching hopefully these developments, among others: hardening of lead alloys containing alkali earths or metals by addition of quicksilver; substitution of quicksilver for tin in production of type-metal alloys; use of the metal in plating iron with lead; adaptation of mercury vapor as a high-temperature industrial heating medium; development of a device using mercury for elimination of scale and corrosion in radiators and cooling systems of automotive vehicles; use of metallic hair tints containing mercury by the cosmetic field; development of a tiny mercury lamp two inches long, thinner than a lead pencil, and emitting a 200-candlepower glare, which may replace the electric arc in movie projectors and is useful also in composing rooms and photographic studios; development of a new method of printing that may be a formidable rival of offset lithography, by which it is possible to print 200-line screen halftones on heavy-ribbed stock, even on sandpaper and textiles.

Increased quantities of mercury were required in 1936 for gold-mining operations in the Western States.

The following table shows the new supply of mercury in the United States, 1927-36:

Supply of mercury in the United States, 1927-36

REVIEW BY STATES

The output of mercury in the United States in 1936 declined 5 percent from that in 1935 despite increased demand and prices. The decline was not evenly distributed over the country as a whole and output in some localities showed rather pronounced improvement. In the important producing areas increased output was made in Arkansas and Oregon, while production declined in California and Texas. The total number of producing properties was relatively stationary for the past 3 years, although there were changes in the actual mines producing, particularly among the smaller ones. The principal producing mines in 1936 were as follows: Arkansas: Pike County—mines of the Mid-Continent Quicksilver Co. and of the Mercury Mining Co.; California: Lake County—Sulphur Bank, Mirabel, and Great Western mines; Napa County—Oat Hill mine; San Benito County—New Idria mine (dumps); and San Luis Obispo County—Oceanic and Klau mines; Oregon: Jefferson County—Horse Heaven mine; Lane County—Black Butte mine; and Malheur County—Bretz and Opalite mines; Texas: Brewster County—Chisos and Rainbow properties. These properties produced 85 percent of the total domestic output of mercury in 1936.

The sharply increasing price for mercury in the latter part of 1936 is reported to have resulted in greater activity at producing mines and in the opening up of idle properties that formerly had produced. One operation that will be watched with particular interest is the reopening, under new ownership and management, of the mine workings of the New Idria mine in San Benito County, Calif. This famous old mine had been idle since 1931, except for the working of old dumps. Old mine workings are now being cleaned out, and one of the four rotary furnaces is being reconditioned for use.

EMPLOYMENT, MAN-HOURS, AND PRODUCTIVITY AT MINES AND PLANTS

The following table indicates the average number of men employed at mercury mines and plants, the time employed, and the approximate output per man-shift and per man-hour for the past 10 years. A short explanation of the trends indicated by the table is contained in the chapter of this series for 1936.

FOREIGN TRADE ⁵

Imports of mercury in 1936 were more than double those reported for 1935, and for the first time since 1928 imports from Italy assumed importance. The total for Italy for 1936 was the largest recorded since 1927, the last full year of operation prior to the formation of the international cartel. From the time the cartel was formed until the beginning of civil war in Spain, broadly speaking, Italy supplied the European demand and Spain the principal part of the demands of the remainder of the world. In 1936, however, the United States received 36 percent of all imported mercury from Italy.

¹ Data not available.² Exports.³ Estimated. ⁴ Figure taken from the Imperial Institute, London.

Germany.—The successful opening up of large reserves of low-grade quicksilver ore at an old mine, the Obermoschel in the Rheinische Palatinate near Bingen, should enable Germany to supply 10 to 15 percent of her requirements in 1937, according to Wright.⁶ He also reported that Germany's imports of mercury were 357 metric tons in 1932, 488 in 1933, 650 in 1934, 869 in 1935, and 455 in the first 6 months of 1936, indicating a substantial increase in consumption of this metal during the period.

Italy.—For many years Italy and Spain have been the principal mercury-producing countries of the world, with Italy leading in some years and Spain in others. The principal mercury resources of the world occur in Spain, but for the 15 years ended in 1934 Italy produced 43 percent and Spain 36 percent of the world total. Production of mercury in Italy in 1935, 28,196 flasks, considerably more than doubled that in 1934 but amounted to only about one-half of the annual average of 56,200 flasks for 1925-29. Statistics showing the quantity of metal produced in 1936 are not yet available, but with the termination of war between Italy and Ethiopia and the added demands of the world for Italian mercury because of the difficulties in obtaining Spanish supplies, it is reasonable to expect a large increase in Italian production.

Exchange difficulties restricted the movement of Italian metal to the United Kingdom and aggravated the unsatisfactory supply situation in that country. The Metal Bulletin (London) reported that Italians were willing to sell but that the British Government insisted that all payments for Italian goods should go through the official exchange clearing, whereas Italian producers, realizing the adverse

⁶ Wright, Chas. Will, *Germany's Capacity to Produce and to Consume Metals, Fuels, and Minerals: Special Suppl. 4, Mineral Trade Notes, Bureau of Mines, Nov. 20, 1936, p. 12.*

balance to Italy of the payments in the clearing were willing to deal only on the basis of direct payment.

At the end of 1936 the Mercury Cartel, Consorzio Mercurio Europeo, which marketed metal through Roura & Forgas, was terminated. It is reported that Italian sales will be made in the future through Amalgamated Merchants, Ltd.

³ Exclusive of output at Cagliari.

Japan.—Only a small part of Japan's mercury requirements is produced at home, as is the case in most large mercury-consuming countries of the world. According to Trade Commissioner Steintorf, Tokyo, October 20, 1936, Japan imported 10,700 flasks in 1933 and 14,500 flasks in 1934. Although figures for 1935 were not available at that time imports for that year were thought to have been 80 per cent above those for 1934, and imports for 1936 were expected to amount to as much as 29,000 flasks. Production amounted to 234 flasks in 1933, 196 in 1934, and 148 in 1935.

The richest mercury mine in Japan is said to be in Yamato Province, although its output is less than 50 tons annually. Steintorf reported that several projects were proposed to increase the output of the country, without very successful results thus far.

Mexico.—The Huitzoco mines in north-central Guerrero were discussed in a paper presented by C. W. Vaupell at the seventeenth annual meeting of Economic Geologists, in New York, February 16-17, 1937. Vaupell stated that production of the mines had been about 90,000 flasks since 1873. Near-surface ores fill extinct mud geysers, and the deep deposits are chambered veins, stockworks in brecciated blocks, and replacements in limestone. The epigenetic minerals—livingstonite, stibnite, and sulphur—occur in limestone, gypsum, and dolomite through a developed vertical range of 260 meters. The deepest workings expose an increased amount of stibnite, which probably indicates that the lower limit of mercury mineralization is being

approached. A resurgence of heat and water formed geysers over an extended area after the period of mercury mineralization. Mud geysers, which are situated in the outcrops, contain secondary mercury minerals, cinnabar, and barcenite in the gravel and mud filling the vents.

A 150-ton flotation plant is in operation concentrating stope fills that assay 3 kilograms of mercury per ton; 150,000 tons are available in one open stope, which is more than 1 hectare in area and 60 meters high.

Spain.—Official data covering operations at the Almaden mine in 1936 are not available. The civil war, with consequent labor and other difficulties, including reported attempts of the rebel forces to gain control of the mercury properties, undoubtedly caused a drop in output. According to rumors the mines were shut down at times during the year. Considerable quantities of mercury shipped from the Almaden mine are reported to have been seized by the rebels, who are supposed to have used part of the metal in payment for arms and munitions.

Output of mercury in 1935 amounted to 35,559 flasks, well above the 1930-34 average, but only 61 percent of the annual average for the 5-year period 1925-29. Exports of 66,340 flasks were considerably above production in 1935, as probably they were in 1936, the difference being drawn from stocks.

According to Consul John D. Johnson, Madrid, May 4, 1936, exports of mercury from Spain from 1931 to 1935 were as follows:

Mercury exported from Spain, 1931-35, by countries of destination

(Flasks of 76 pounds)

	1931	1932	1933	1934	1935
Belgium.....	985	830	1,590	4,570	15,420
Germany.....	1,700	2,870	4,530	2,560	7,260
United Kingdom.....	6,630	9,090	11,730	11,670	19,370
United States.....	600	4,700	16,820	6,080	10,110
Other countries.....	3,675	6,640	7,230	8,730	14,180
	13,590	24,130	41,900	33,610	66,340

Johnson's report stated that the largely increased exports in 1935 were attributed by interested sources in Spain to the desire of importing countries to increase their stocks of metal, because of unsettled world conditions and consequent uncertainty as to the possibility of future purchases and deliveries.

Turkey.—Demand for mercury in 1936 was brisk, and principally from Japan, Great Britain, and Germany, according to Commercial Attaché Julian E. Gillespie, Istanbul. There was increased activity at the mines on the Karaburnu Peninsula, at the entrance to the Gulf of Smyrna, in an unsuccessful effort to fill the large orders received. It was reported that an order from Great Britain for 2,500 flasks had been refused. In the third quarter of the year the mine was operating at capacity in an attempt to fill an order for 500 flasks, supposedly from Germany and at a reported price of £15.

U. S. S. R. (Russia).—If reports are correct, a large increase in output of mercury in Russia is indicated. From a recent high of 3,771 flasks in 1929, output increased to 6,700 in 1933 and 7,750 in 1934.

The year 1936 was noteworthy for the tin industry. The international restriction scheme was renewed, production and consumption increased, and financial statements were in general correspondingly better. However, the year was not without its adverse phases. Stocks remained low throughout the year; and the average price was lower than in 1935, although this situation righted itself in the last quarter. Demand for tin did not increase notably anywhere except in the United States where the increase was due to demands of the tin-plate and automobile industries. Generally unrewarded search for new tin deposits continued in several regions throughout the world. Progress was made, however, in the development of substitutes for tin (synthetic resins, aluminum, etc.). Owing to the export demand for tin-plate clippings (scrap) and the rise in price, the United States placed an export license on this commodity.

¹ Subject to revision.

² Figures for 1932-36 cover foreign only; domestic not separately recorded.

Figure 40 illustrates the salient features of the tin industry since 1900. The most important feature of the chart is the parallelism between the price curve and the United States tin-imports curve; the price curve shows a definite tendency to rise and fall as the world's visible stocks decrease and increase. Stocks in the United States, although small and, from a world standpoint, virtually insignificant, nevertheless parallel the course of world visible stocks in a general

way. It is evident that consumption or demand in the United States largely determines the state of the tin-mining industry. It will be noted that mine production shows an upward tendency, but this is less intense than that for many other metals.

Third international production-control agreement.—The dominant question before the tin industry in 1936 was the renewal of the international cartel or restriction agreement. The Tin Committee, at its meeting in London on May 26, 1936, announced that Bolivia, Malaya, Netherland India, and Nigeria were willing to continue control on an agreed basis, if outside countries would satisfactorily limit their production. Siam demanded an increase in its quota to 18,000 to 20,000 long tons a year. The committee demurred, and its delegates, V. A. Lowinger and J. van den Broek, were sent to Siam to negotiate with the Siamese Government for the renewal by the People's Assembly of the restriction scheme. Eventually the Siamese Government signified its willingness to agree to the pact; it was agreed that the quota should be 18,000 tons, and the Tin Committee announced its decision on November 5, 1936. Even then the terms were not accepted by the Siamese People's Assembly until December

FIGURE 40.—Trends in production, imports, stocks, and prices of tin, 1901-36.

28, 1936, and the industry entered the new year uninformed as to the nature of the agreement until it was signed at Brussels on January 5, 1937; the details were made known at a still later date.

Several important differences should be noted between the old and the new agreements. The most important difference is that in the old agreement the unanimous vote of the delegates was necessary to fix the quota; in the new agreement the unanimous vote is to be replaced by a majority vote of the representatives. The number of votes available for a country is based on the relative importance of its tin-production industry: Malaya thus receives five votes, Bolivia four, Netherland India four, Siam two, Belgian Congo two, Nigeria two, and Indochina one. A total of 11 votes of the 20 will carry any proposal. Under the new agreement the committee will have plenipotentiary powers to fix quotas instead of merely recommending suggestions for the approval of the governments concerned. The two leading nations that consume tin will be represented on the council, but they will have no right to vote. The representative of the United States is John Hughes, past president of the United States Steel Products Co., and the representative of the United Kingdom is Sir William Firth.

If the production of all countries not included in the agreement exceeds either 15 percent of the world's estimated production or 12,500 long tons of tin for 6 consecutive months, any signatory country may give 6 months' notice of its intention to withdraw from the agreement. If any country becomes involved in hostilities it may apply to the committee to be allowed to export temporarily more than its permissible output. If permission, which must be accorded by unanimous vote, is refused, such country may withdraw from the scheme. Another clause provides that production and export shall be controlled during the year to correspond with the quota. This excludes the possibility of building up any unexported stock, such as a buffer pool. In the event of serious underexports signatory countries may carry forward to the next year only 8½ percent of their permissible exports during that year. Excess exports, on the other hand, are carried forward in full and subtracted from the succeeding year's quota. Any renewal of the agreement must be recommended not more than 12 nor less than 9 months prior to December 31, 1941. The signatories again give as their object the regulation of production and exports from producing territories, the adjustment of output to consumption, the prevention of severe fluctuations in price, and the maintenance of reasonable stocks.

Standard tonnages under the third agreement remain the same for Bolivia, Malaya, Netherland India, Nigeria, Cornwall, and Portugal. Siam's tonnage is computed on the basis of the true assay value $\left(\frac{a}{72} \times 18,500\right)$. The difference between the figure thus obtained and 18,000 long tons is met by a reduction of the standard tonnages of Bolivia and Belgian Congo in the ratio of 2.8 to 1. The minimum export for Siam is calculated by the formula $\left(\frac{a}{72} \times 11,100\right)$. The difference between the figure thus obtained and the agreed minimum export of 10,500 tons is also met by a reduction of the standard tonnages of Bolivia and Belgian Congo in the ratio of 2.8 to 1. Indochina shall not be required to produce at a rate less than 1,800 tons a year on a true assay basis.¹

¹ For record of plan from its beginning in 1931 through 1935, see Minerals Yearbook, 1935, p. 516, and Minerals Yearbook, 1936, p. 472.

² Data not available.

³ No restriction of output.

⁴ International Tin Research and Development Council, Stat. Bull., vol. 5, no. 2, 1937, p. 3.

Tin-plate-scrap export restriction.—Tin-plate scrap is one of the most important raw materials used in the production of secondary tin. To safeguard the domestic detinning industry, which was threatened with the loss of its source of supply by the recent increase in exports of tin-plate scrap, Congress passed the Faddis bill (S. Res. 3381) prohibiting the export of this commodity except under license. The bill was signed by the President on February 15, 1936.

In a press notice the Department of State reports requests for allotments totaling 91,584 long tons of tin-plate scrap for export from July 1 to December 31, 1936.² Allotments totaling 9,524 tons were granted in conformity with the provisions of the statement of the procedure, announced June 15, 1936. Applications for license to export, between July 1 and December 31, 1936, a total of 23,383 long tons of tin-plate scrap were received and acted upon by the Department. Forty-nine licenses were issued, authorizing the exportation during that period of 6,483 long tons of tin-plate scrap valued at \$106,854. These licenses were for export to Japan only. Allotments that total 18,609 long tons of tin-plate scrap have been assigned to 39 producers for export, subject to license, during the calendar year 1937, in accordance with the provisions of the statement of procedure announced by the Acting Secretary of State on December 7. Applications for allotments totaling 27,752 long tons were received, some of which necessarily were reduced to comply with the requirements set forth in the announcement of December 7, 1936.

Tin-plate scrap exports from the United States in 1936 totaled 14,375 long tons valued at \$282,214. In 1935 exports of tin-plate scrap were 34,928 long tons valued at \$749,604. Waste-waste-tin-plate exports in 1936 were 80,805 long tons valued at \$2,635,662. In 1935 exports of tin-plate scrap to Japan totaled 31,961 long tons, and waste-waste-tin-plate exports totaled 20,869 long tons.

DOMESTIC PRODUCTION AND RESOURCES

Primary tin.—The domestic mine output of tin from Alaska in 1936 was 102.6 long tons valued at \$106,700, calculated on the average price for straight cassiterite. The continental United States produced 60 pounds of cassiterite, all from South Dakota. It is said that the dry summer adversely affected proposed placer mining in that State. Since the beginning of careful statistical compilation in 1902 the tin production of the United States has amounted to 1,365 long tons, of which only 289 long tons have come from continental United States; the remainder (1,076 long tons) was derived from Alaska. It has required 35 years to produce this quantity of tin, whereas the minimum annual consumption of virgin tin in recent years was 35,478 long tons in 1932.

² U. S. Department of State, Press Release: Vol. 16, no. 380, Jan. 9, 1937, pp. 19-20.

A recent description of the Alaska tin deposits, by Philip S. Smith, has been published by the United States Geological Survey.³

Secondary tin.—Production of secondary tin in the United States amounted to 25,000 long tons, which was equivalent to 33 percent of the imports of virgin tin imported as metal. The amount of secondary tin recovered showed a slight increase of 100 long tons, or 0.4 percent over the recovery in 1935.

IMPORTS AND EXPORTS⁴

Metal and ore.—Tin concentrates continued to occupy a negligible position in the tin trade, imports amounting to only 179 long tons in 1936. Tin concentrates from the Seward Peninsula, Alaska, were exported to Singapore, Straits Settlements, and Liverpool, England. Such shipments in 1936 totaled 344,774 pounds of concentrates, which averaged 66.6 percent tin (229,734 pounds of metal). In 1935 shipments were 173,774 pounds, which averaged 65.7 percent tin (114,182 pounds of metal).

⁴ Smith, Philip S., Mineral Industry in Alaska in 1935: U. S. Geol. Survey Bull. 880-A, 1937, pp. 75-77.

⁵ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from the records of the Bureau of Foreign and Domestic Commerce.

Importation of 76,030 long tons of tin (bars, pigs, blocks, grain, granulated, or scrap, and alloys, chief value tin, n. s. p. f.) in 1936 represent an 18 percent increase over 1935. British Malaya supplied 71.5 percent of the total in 1936, an increase of 46.1 percent over 1935 imports from the Straits and the United Kingdom furnished 11.1 percent, a decrease of 45.8 percent from 1935 imports from the United Kingdom.

During 1936 exports (in reality reexports) of metallic tin amounted to 386 long tons, a marked decrease from the 2,292 tons exported in 1935 and a very small quantity compared with imports of tin.

Tin manufactures.—Imports of tin plates, terneplates, and taggers tin were 233 long tons valued at \$62,048 in 1936 compared with 187 long tons valued at \$48,867 in 1935. The United Kingdom furnished 218 tons or 94 percent of the 1936 imports.

CONSUMPTION AND USES

According to the International Tin Committee⁵ the world consumption of tin in 1936 totaled 157,000 long tons compared with 142,044 tons in 1935, an increase of 10.5 percent. The ratio of total visible supply and carry-over (Straits and Arnhem) to tin consumption was 14.4 percent in 1936 compared with 9.7 percent in 1935.

Record increases in consumption in 1936 are noted in Japan, with 6,411 long tons; Poland, 1,322 tons; and Denmark, 690 tons. On the other hand, consumption in Germany decreased 18.8 percent, from 10,419 to 8,462 tons. The United States increased its consumption of tin from 62,292 long tons in 1935 to 75,643 in 1936, or 21.3 percent. Invisible stocks in the United States were 7,000 long tons at the beginning of the year and increased to 12,000 tons, only to decline at the end of the year to about 9,000 tons. According to the International Tin Committee distribution of consumption by uses was as follows: Tin plate, 35,770 long tons; solder, 11,880; bronze, collapsible tubes, and foil, 11,800; automobiles, 10,000; babbitt, 3,690; and other manufactures, 9,150.

⁵ International Tin Research and Development Committee, Stat. Bull., vol. 5, no. 2, 1937, pp. 7-16.

The Bureau of Mines conducted a survey of the consumption of primary and secondary tin in the United States during 1935.⁶ Questionnaires were sent to 947 concerns which reported consumption of 70,962 long tons of tin, including 55,779 tons of primary or virgin tin and 15,183 tons of secondary tin. Stocks on hand January 1, 1935, were 16,579 long tons and net purchases 71,188 tons, so that 87,767 tons were available for use in 1935; stocks as of December 31, 1935, were 14,649 long tons. Deductions for intercompany transactions in scrap in terms of tin content were 1,805 tons, while losses accounted for 351 tons. The consumption (70,962 tons) of tin by uses was as follows: Tin plate, 27,290 long tons; terneplate, 1,012; solder, 16,646; babbitt, 5,144; bronze, 4,765; collapsible tubes, 3,548; chemicals (other than tin oxide), 3,205; tinning, 2,082; foil, 1,629; tin oxide, 1,249; type metal, 1,003; pipe and tubing, 953; galvanizing, 620; miscellaneous alloys, 481; white metal, 397; bar tin, 395; and miscellaneous, 543.

³ Figures for Jan. 1 and Dec. 31 are stocks at beginning and end of the 5-year period and not averages of stocks on Jan. 1 and Dec. 31 of each year during period.

⁴ Figures for 1932-36 cover foreign exports only; domestic exports not separately recorded.

Tin plate and terneplate.—According to the American Bureau of Metal Statistics the production of tin plate in the United States in 1936 was 2,096,699 long tons compared with 1,692,380 tons in 1935.⁷ This tonnage required 36,694 long tons of tin, or 1.742 percent by weight—a total of 39.02 pounds of tin per gross ton. The use of tin in pounds per gross ton has increased continuously for a number of years (from 34.45 pounds per ton in 1929). The United States is reported also to have produced 253,858 tons of terneplate, which required 1,535 tons of tin, or 0.605 percent—a total of 13.55 pounds of tin per gross ton.

The International Tin Committee reports world production of tin plate at 3,779,000 tons compared with 3,144,000 tons in 1935.

Automobile manufacture.—According to the Bureau of the Census factory sales of vehicles of all kinds totaled 4,454,535 in 1936 compared with 3,946,934 vehicles in 1935. Exports of all classes of motor vehicles totaled 287,810. At the close of the year the outlook of the

⁶ Pehrson, E. W., Umbau, J. B., and Trought, M. E., Consumption of Primary and Secondary Tin in the United States: Inf. Circ. 6930, Bureau of Mines, 1936, 12 pp.

⁷ American Metal Market, vol. 44, no. 70, Apr. 14, 1937, p. 3.

automobile industry was somewhat uncertain owing to labor difficulties. In spite of the increase in the number of automobiles manufactured in recent years, there has been a steady decline in the consumption of tin per vehicle. In 1930, 8,010 pounds of tin were used per car (3,355,986 vehicles), but in 1936 only 5,108 pounds of tin were used per car (4,454,535 vehicles). This decrease is due to the substitution of other metals, notably cadmium, for tin.

Other uses.—Essential data on the can- and tinware-manufacturing industries were given in a recent Bureau of the Census report.⁸ The International Tin Committee, in cooperation with Battelle Memorial Institute, issued an informative illustrated description of tin-plate, bottle-cap, and closure manufacture and of the canning industry in the United States.⁹

The marketing of beer in cans increased during 1936. The advantages of canned beer are lower freight charges, no sorting and washing of bottles, elimination of consumer deposit, no breakage, and no deterioration of contents by exposure to sunlight. Vacuum packaging in tin containers is now being used for tobacco, coffee, typewriter ribbons, medicated tablets, and tooth powder. Apparently there is a trend for consumers to prefer tooth powder in cans, a market largely lost since the war.

PRICES AND STOCKS

Prices.—Although the highest price for tin in 1936 was near that for 1935 the low price was much lower. The average price also showed a marked decline. In May the growing deficiency in the quota assigned to Bolivia and the dissatisfaction of Siam led to apprehensions regarding the renewal of the agreement, which were reflected by the price situation in international markets. Low prices during the year were on June 26 and July 2, after which the price slowly rallied, influenced by the favorable trend in negotiations with Japan. On November 5 the renewal of the tin agreement was announced. Prices rose to the high point of the year on November 9 but declined slightly immediately thereafter. Quotations continued firm throughout the rest of the year, largely owing to general business improvement and rearmament demands in Europe.

Stocks.—According to the Tin Committee world visible supply and carry-over amounted to 13,841 long tons at the beginning of the year and 22,695 tons at the end.¹⁰ Stocks within the United States increased from 2,312 to 5,095 tons.

In February stocks in the United Kingdom reached such a low point that the London Metal Exchange protested to the Colonial Secretary, who returned a noncommittal reply. Nevertheless stocks reached a record low level, for on April 4, 1936, they amounted to only 369 tons. Floods in the Pittsburgh district eased the American stock position.

¹ Metal Statistics, 1937, pp. 349 and 351. Beginning January 1930, figures for world stocks include carry-over in the Straits Settlements (on lighters and warrants); beginning July 1933, they also include carry-over at Arnhem (Netherlands) smelter.

WORLD PRODUCTION AND RESOURCES

World production of tin-in-ore in 1936 amounted to 180,000 long tons, an increase of 32.4 percent over the 136,000 tons produced in 1935. It is to be noted that both the total and certain production figures (notably for Australia, Belgian Congo, China, Indochina, Japan, Mexico, Netherland India, and Portugal) differ from those published by the International Tin Committee in its monthly Statistical Bulletin. The Bureau of Mines figures are compiled on the basis of the various official national statistical reports, official consular inquiries, and sundry trade information. The figures used in the following discussion for production in 1936 are those of the Tin Com-

¹⁰ International Tin Research & Development Council: Stat. Bull., vol. 5, no. 2, February 1937, p. 16.

mittee. This committee reports the total world production of tin in 1936 as 171,888 long tons compared with the rounded figure of 180,000 long tons of the Bureau of Mines.¹¹ If the figures of the Tin Committee, published for comparative and regulatory purposes, are accepted it will be noted that production of the signatory countries was 153,556 tons or 89 percent of the total world production.

A comparison of the quota of 172,920 tons for 1936 and the actual production of signatory countries of 153,556 tons reveals a deficiency of 19,364 tons, 10,288 tons of which Bolivia surrendered at the end of May 1936. Production quotas were then raised for the other countries, but, even so, 1936 closed with a world gross deficiency of 9,322 tons, and a world cumulative deficiency total of 3,333 tons was carried forward. Although the Bolivian underproduction was re-assigned, the deficit incurred by Bolivia in the months following May, combined with deficiencies in production of Indochina, Netherland India, and Nigeria, were insufficient to balance the small excess (698 tons) tonnage of Belgian Congo, Malaya, and Siam.

World production of tin (content of ore), 1925-29 (average) and 1932-36, by countries, in long tons

A comprehensive digest of post-war changes in world tin mining was prepared by Josef Wollnik.¹²

A more critical study of the contemporary situation in the tin industry with a brief review of its antecedents was contributed by J. K. Eastham,¹³ an opponent of the restriction plan.

TIN-MINING COUNTRIES

British Malaya.—The tin-restriction agreement in Malaya has stopped development and prospecting and has caused the industry to move in a routine manner. Formerly the duty was levied on an assumed assay value of 72 percent, but under the restriction scheme

¹¹ International Tin Research & Development Council: Stat. Bull., vol. 5, no. 2, February 1937, p. 5.

¹³ Eastham, J. K., Rationalization in the Tin Industry: London, vol. 4, no. 1, 1936. pp. 13-32.

this value seems inaccurate, and in 1935 the assay value averaged 75.56 percent. These high percentages suggest that the earlier totals of Malayan production were generally underestimated.

Tin is mined by almost all known methods. Production in 1936 by dredges amounted to 30,445 long tons of fine tin; gravel pumping, 24,833 tons; hydraulicking, 3,149 tons; open-cast mines, 2,558 tons; shafts in alluvial deposits, 684 tons; dulang washers, 1,028 tons; and from samples and sweepings, 60 tons.

The number of persons employed in the tin mines showed a continuous increase during the year (according to monthly figures), reaching a peak of 78,714 in December, compared with 65,328 in December 1935 and 53,037 in December 1934.

The Japanese firm, Ishihara Sangyo Koshi, Ltd., continued development work in its hematite concession at Pelepah Kanan in the State of Johore. This iron-ore deposit carries profitable values in tin, the iron ore being available as a byproduct. The tonnage is not as yet known but it is reported to be very large. Lode deposits of tin other than those of Pahang are very rare, and if this deposit proves profitable, the prospecting for tin other than alluvial may be expected to be intensified.¹⁴ Examinations were made of possible dredgable deposits in several inland areas in the Dindings, the district between Kinta Valley and the coast.

Netherland India.—The geology of the lode and detrital deposits of Netherland India was described by Wing-Easton.¹⁵ The Government-owned and operated Banka mines and the Billiton Tin Co. (a joint Government and private enterprise) are reported to be negotiating for an amalgamation of interests. Vereenigde Nederlandsche Tinbedrijven, the new company, will have a capital of 55 million florins, of which 4,950 shares valued at 10,000 florins each will be held by the Government and the remainder by the Billiton Co.

Bolivia.—The genesis and mineralization of the Bolivian tin belt have been reviewed by Ahlfeld.¹⁶

The report of the Bolivian Tin Investigation Committee, dated January 31, 1936, contains a wealth of data concerning the organization, operations, and costs of the tin-mining companies of Bolivia.¹⁷ The committee concluded that the tin industry in Bolivia is capable of producing the quota which the international agreement assigns to it; that it is urgent to study and modify the mining laws to facilitate development of the industry through simplification of (legal) procedure; and that it is necessary to create a special organization which will serve as a contact between public authorities and producers. The committee points out further that Bolivia must promptly fulfill the quota assigned by the rationing plan and use all mechanical methods to produce the greatest amount of tin at the lowest cost. Also that the freight rates should be investigated and revised.

A. E. Donovan, Second,¹⁸ American vice consul located at La Paz, reports that a contract was signed on December 24, 1936, between the Bolivian Government and Mauricio Bony & Co. for the establishment of tin-ore smelters in Bolivia.

¹⁸ U. S. Bureau of Mines, *Mineral Trade Notes*, vol. 4, no. 3, Mar. 20, 1937, pp. 12-13.

By the Exchange Decree of March 31, 1936, the Government paid the miners approximately 37.50 bolivianos per pound sterling for ore delivered after March 31, 1936, instead of 20.00 bolivianos per pound, as during the previous months. A new decree was issued on September 5, 1936, with the provisions that the miners must deliver an additional 10 percent in drafts.

Siam.—Tin mining in Siam is particularly important in the areas of Bhuket, Nakorn Sritamarat, Rajaburi, and Pattani. H. G. Minnigerode,¹⁹ the United States vice consul, reports that there are 21 dredging companies with 28 dredges in operation. Four additional companies are preparing to begin operations, and 10 more dredges are under construction. Prior to 1928–29 some tin ore was smelted in Siam, but smelting has now all but stopped, and the output is shipped either to Penang or Singapore for smelting.

China.—It is reported that the Kotchiu smelter in Yunnan Province, China, is being further enlarged. During 1935 the smelter produced about 2,000 tons of tin, and production during 1936 has been on a still larger scale.

In the Hunan Province cassiterite-arsenopyrite deposits occur as pipelike deposits in dolomitized limestone.²⁰

Belgian Congo.—At present tin is produced in the Provinces of Costermansville and Elisabethville, Belgian Congo. The Géomines, using electrical smelting methods, produced 1,588 tons of metallic tin for the first time in 1935. The remainder of the ore produced in Belgian Congo is shipped to Hoboken, Belgium, for smelting.

Burma.—The Government of Burma has authorized a geological survey of an area of about 2,000 square miles in the Southern Shan States by the Mawchi Mines, Ltd., of London. This area is in the same zone as that now being exploited for tin and tungsten by the same company. The company has invested additional money in a plant to treat tailings from the Mawchi mill and in equipment for working alluvial deposits, which are estimated at 1,000,000 cubic yards.²¹

Australia.—The concentration of tin ores of Australia was the subject of considerable discussion during the year.²² Descriptions were published of the Torrington tin field, the largest in New South Wales,²³ and of the alluvial mining area at Eldorado near Wangaratta, Victoria.²⁴ The latter area is being opened up as a result of renewed activity in gold mining with dredges. Two new companies (Anglo Tasman Development Co. and Tasmanian Amalgamated Tin Mines) were organized to work part of the Renison Bell pyritic tin deposits on the west coast of Tasmania. These ores aggregate more than 1,000,000 tons and assay about 0.6 percent metallic tin. The treatment of these ores is under investigation.²⁵

TIN SMELTERS

During 1936 the recent tendency to expand and enlarge existing smelter facilities received additional impetus. A new (the fourth) furnace is being constructed at the Arnhem smelter in the Netherlands and will be completed by August 1937. The Kotechu smelter in southern China is being enlarged. In 1935 the electrical smelting of tin was begun in the Belgian Congo. Likewise tin smelting was begun in Argentina. Negotiations are in progress to construct a smelter in Bolivia. A new smelter is almost completed near Liverpool, England.

Domestic consumption of white arsenic reached a new peak in 1936. Sales by domestic producers nearly equaled the previous record of 1934, and imports were the highest ever recorded. The extension of the market for this product has been due to its effectiveness as an insecticide and weed killer. In 1936 these uses took 85 percent of the total consumed.

The world output in 1936 continued at approximately the same level established in the previous year. Production in Sweden still exceeds market demands, and the problem of storing the excess output is becoming acute.

¹ Includes sales by domestic producers for export.

² 10,467 pounds in 1925 and 200 pounds in 1929; no imports from 1926 to 1928, inclusive.

³ Average for 1928-29; exports of calcium arsenate and lead arsenate not separately recorded by Bureau of Foreign and Domestic Commerce prior to 1928.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

PRODUCTION

The 1936 domestic production of 15,379 short tons of arsenious oxide (As_2O_3 , white arsenic) was 8 percent more than the 14,237 tons produced in 1935. The tendency of producers to market more of their product crude was continued in 1936. Of the total sales, 56 percent was crude arsenic and 44 percent refined arsenic. In 1935, 55 percent of the total sales was crude. Much of the arsenic classified as crude, however, closely approximates a refined product, averaging better than 98 percent purity. Producers designated their output as refined white arsenic, crude white arsenic, refinery crude, flue dust (black arsenic), wood-preserver paste, and weed killer. The United States producers are Anaconda Copper Mining Co., American Smelting & Refining Co., Jardine Mining Co., and United States Smelting, Refining & Mining Co.

Average receipts from sales, as reported by domestic producers, were 1.52 cents per pound for crude arsenic and 2.58 cents for refined arsenic. Of the 15,581 short tons of white arsenic sold in 1936, 8,755 tons valued at \$266,113 were sold as crude and the balance (6,826 tons valued at \$352,713) as refined white arsenic.

CONSUMPTION

The total supply of white arsenic in 1936 amounted to 33,166 short tons, 20 percent more than in 1935. Of the 1936 total, 47 percent was derived from domestic production and 53 percent from imports. Exports, as reported by domestic producers, were about 1,000 short tons in 1936 and 800 tons in 1935, leaving a net consumption of 32,166 short tons in 1936 and 26,945 tons in 1935.

In addition to the white arsenic consumed in the United States, many arsenic products are imported for consumption; details are shown in the salient statistics table at the beginning of this chapter.

White arsenic is used for a variety of purposes. Each year the Bureau of Mines asks domestic producers to distribute their sales according to uses. Although the results represent only approximations, they show in general the importance of various industries as consumers of arsenic. The distribution in 1936 was as follows: Insecticides, 67 percent; weed killer, 18; wood preservative, 4; glass industry, 3; miscellaneous, 1; and exports, 7.

Since most of the white arsenic is consumed as an insecticide and weed killer, demand is heaviest in the spring and summer. No important new uses for arsenic were developed during 1936.

The principal arsenical insecticides are calcium arsenate ($\text{Ca}_3(\text{AsO}_4)_2 + 3\text{H}_2\text{O}$) and lead arsenate ($\text{Pb}_3(\text{AsO}_4)_2$). Large quantities of calcium arsenate are used to poison the cotton-boll weevil in the Southern States; it is also used as a germicide and fungicide. Lead arsenate is used as an insecticide either directly or as an ingredient of various preparations. Sodium arsenate ($\text{Na}_2\text{AsO}_4 \cdot 12\text{H}_2\text{O}$) is used in manufacturing lead arsenate, in insecticidal and germicidal compounds, drying colors, printing inks, and medicine, and as a mordant in dyeing and printing textiles. Sodium arsenite (NaAsO_2) is used in manufacturing insecticides, soaps, dyeing textiles, preserving hides, and general antiseptics. Since 1934, when the Government began to help combat the grasshopper menace in the drought-stricken West and Middle West, much sodium arsenite solution has been consumed

for grasshopper bait. Sodium arsenite is used extensively as a weed killer, and in Australia it is employed to kill green timber during the clearing of land.²

The domestic consumption of insecticides and fungicides during 1934,³ which holds approximately true for 1935 and 1936, included the following arsenicals: Lead arsenate, 40,000,000 pounds; calcium arsenate, 30,000,000 pounds; paris green (copper aceto-arsenite), 4,000,000 pounds; white arsenic for grasshopper bait, 7,924,000 pounds; sodium arsenite solution (32 percent As_2O_3) for grasshopper bait, 175,000 gallons. In addition, considerable quantities of the following were used: Zinc arsenite, magnesium arsenate, manganese arsenate, arsenical cattle dip; and sodium arsenite (used as a weed killer). Calcium arsenate contains approximately 40 percent As_2O_3 and lead arsenate about 30 percent As_2O_3 .

The most important use of metallic arsenic is in arsenical copper, where it increases corrosion and erosion resistance, raises the annealing temperature, and perhaps serves as a deoxidizer. Arsenical copper is used to a great extent in Europe for locomotive-firebox staybolts and plates. In this country it is used in automobile radiators and other manufactured products assembled by soldering because of its higher annealing temperature. Arsenic is also used in the manufacture of lead shot, lead-antimony alloy anodes, railway brasses, muntz metal, and speculum metal for mirrors of reflecting telescopes; some is also consumed in lead-tin alloy bearing metals.

PRICES

The total value and the average price received by producers from sales of crude and refined white arsenic are stated in this chapter under Production. The following table shows the range of quotations for various arsenic compounds. No appreciable changes were recorded in 1936.

Range of quotations on arsenic and its compounds at New York (or delivered in East), 1935-36¹

	1935 (cents)	1936 (cents)
Arsenic metal, lump, cases..... per pound.....	40.00-48.00	42.00-48.00
White arsenic (As_2O_3), domestic, kegs, carlots..... do.....	3.50	3.50
White arsenic, Japanese, cases..... do.....	3.50-4.50	3.75-4.50
Red arsenic, (As_2S_3), imported, cases..... do.....	15.75-16.50	15.75-16.25
Calcium arsenate, wholesale, drums, carlots..... do.....	6.00-6.60	6.00
Lead arsenate, wholesale, drums, carlots..... do.....	9.00-9.50	9.00-9.38
Sodium arsenate, drums..... do.....	9.50-11.60	9.50-11.50
Sodium arsenite (liquid), drums..... per gallon.....	40.00-75.00	40.00-75.00

¹ As reported by Oil, Paint, and Drug Reporter.

FOREIGN TRADE

The amount of white arsenic imported for consumption in 1936 increased 17 percent and was the highest on record; of the total, Mexico supplied 46 percent, Sweden 36 percent, Belgium 6 percent, Japan 5 percent, and Australia 4 percent. Of outstanding interest was the large importation of arsenic from Sweden. Mexico, however, continued to be the principal foreign source of supply.

² Imperial Institute, *Some Metallic and Inorganic Compounds Used as Weed Killers*: Bull., vol. 34, no. 2, April-June 1936, pp. 195-197.

³ Roark, R. C., *Insecticides and Fungicides*: Ind. and Eng. Chem., vol. 27, no. 5, May 1935, pp. 530-532.

Imports of arsenical compounds other than white arsenic in 1936 appear in the table of salient statistics. Imports of metallic arsenic increased 27 percent over those in 1935, calcium arsenate 347 percent, and sheep dip 37 percent, whereas receipts of arsenic sulphides decreased 50 percent, paris green and london purple 13 percent, and sodium arsenate 59 percent.

Official export data for white arsenic are not available, but reports of individual domestic producers indicate that about 1,000 short tons were sold for export in 1936, compared with about 800 tons in 1935; the normal total in previous years was about 2,000 tons. Exports of calcium arsenate in 1936 increased 53 percent while exports of lead arsenate decreased 28 percent.

WORLD PRODUCTION

World production of white arsenic in 1936 remained approximately at the 1935 level. Virtually all of the world's arsenic is produced as a byproduct in the treatment of gold, copper, lead, zinc, cobalt, silver, tungsten, and tin ores.

World production of arsenic ore and white arsenic, 1932-36, in metric tons

¹ Gross weight. Arsenic content not stated.² Data not available.³ Exports of domestic product.⁴ Includes arsenopyrites, mispickel, and realgar.

Argentina.—Sodium arsenate has been found effective in poisoning the locusts in Argentina, which are said to destroy 30 percent of the annual agricultural crop. The Argentine Ministry of Agriculture has a small chemical plant near Buenos Aires for the production of sodium arsenate.

Australia.—White arsenic is recovered chiefly from the arsenopyrite in the gold ores of Western Australia and New South Wales. Some arsenic is obtained from the tin concentrates of the Ottery mine at Tent Hill. A. Victor Leggo, Ltd., produces most of the country's arsenic from ore of the Wiluna gold mine at Wiluna, Western Australia. In the process, roaster gases from heated flotation concentrates are drawn by a multivane fan into a condensing plant consisting of a series of concrete chambers equipped with a system of baffles. The remaining gases are treated further in a Lodge-Cottrell precipitator before passing to the main stack.

Belgium.—White arsenic produced by the Société Générale Métallurgique de Hoboken at its Reppel works is derived from speiss obtained from the furnaces at Hoboken. Much of the arsenical ore probably originates at the copper properties of Union Minière du Haut-Katanga in the Belgian Congo.

Brazil.—The white arsenic of Brazil is derived chiefly as a byproduct from the gold ores of the St. John del Rey and Ouro Preto mines.

Canada.—Refined white arsenic and arsenical insecticides are made from the cobalt-silver-arsenic ores treated by the Deloro Smelting & Refining Co., Ltd., Deloro, Ontario. A baghouse to extract arsenic from the fumes of a small roasting plant used in the treatment for the recovery of gold was put in operation in the fall of 1935 by the O'Brien Gold Mines, Ltd., Cadillac Township, Quebec. The Beattie mine, Quebec, and the Bralorne mine, British Columbia, ship arsenical gold concentrates to the United States. Some of the arsenical gold concentrates in Nova Scotia are also treated for their arsenic content.

China.—Arsenic is found chiefly in the Provinces of Hunan and Yunnan. Most of the arsenic occurs as arsenopyrite, orpiment, and realgar, and some of the mines are worked solely for arsenic. The Hunan production, however, is a byproduct from the ores of tin, lead, zinc, antimony, and tungsten.

France.—The Combe-de-Saut plant of the Société des Mines et Usines de Salsigne recovers an estimated 10,000 metric tons of arsenious oxide annually from the gold-bearing arsenopyrite and pyritic ores mined in the Department of Aude.

Germany.—The Arsenic Mining & Smelting Works "Reicher Trost" at Reichenstein each month normally treats approximately 2,200 metric tons of arsenic ore, which is derived from the arsenopyrite deposits at Reichenstein, Altenberg, and Rothenburg in Silesia. The company furnishes much of the German output of white arsenic and also controls a chemical plant (Chemische Fabrik Wilhelmsburg at Harburg-Wilhelmsburg) with a monthly production capacity of 350 tons of insecticide. The Müldenhütten plant near Freiberg treats arsenical ores from the Mansfeld copper mines and imported ores.

Japan.—Although most of the Japanese arsenic output is recovered as a byproduct in the smelting of copper and lead ores, numerous small mines are operated for their arsenic product alone.

Mexico.—The white arsenic of Mexico is a byproduct from smelters of the Cia Minera de Peñoles, S. A. (American Metal Co.), at Torreón, Coahuila, and the American Smelting & Refining Co. at San Luis Potosí. The American Metal Co. production is important in the United States arsenic market.

Sweden.—The Bolidens Gruv AB., the largest producer and holder of arsenic in the world, maintains a laboratory at Stockholm for research on new uses for arsenic. Some success has been achieved, especially in the fields of insecticides, timber preservation, and corrosion-resistant concrete. It is said that the company now holds stocks of approximately 295,000 metric tons of arsenious oxide (As_2O_3). The sulphide ores at Boliden average about 0.6 ounce gold, 2 ounces silver, 1.8 percent copper, 30 percent sulphur, and 9.1 percent arsenic. Arsenious oxide is recovered from the roaster gases at Rönnskär by cooling and precipitation. A small part of the crude arsenic is refined, and the rest is stored in a huge concrete silo. The two methods used for refining include resublimation of crude arsenic in a small reverberatory furnace fired by producer gas and a special wet process. Crude-arsenic production is reported to average 40,000 metric tons annually; the export market is able to take only about 7,000 tons.

Arsenic is being used as a preservative for telephone poles and lumber. In investigating the value of different arsenic compounds as fungicides for wood preservation, it has been found that zinc arsenate is the most efficient and economical. It is applied preferably by double impregnation, first with sodium arsenate and afterward with zinc chloride. Zinc arsenate is thus precipitated in the wood tissues.⁴ Experiments by the Zoological Marine Laboratory at Kristineberg show that arsenic-impregnated wood is free from damage by shipworms. Piles and other timber under water are preserved by an arsenic concrete spray. The Royal Board of Roads and Water Constructions has found that spraying an arsenic-concrete compound on wooden poles is more expensive than impregnation. A hydraulic cement, with aluminum arsenate as the principal constituent, has been developed by Boliden. It is said that this cement is especially effective for railway ties and sewage piping.

The Boliden company recently received patents on complex ammonia arsenic salts for the protection of plants and trees against fungi and insects. These salts, containing arsenic as well as another metal and ammonia, are said to be rather insoluble and, therefore, are superior to some arsenic sprays that contain or that form acid components injurious to the green parts of plants and trees.⁴

United Kingdom.—White arsenic and arsenic soot are recovered in the treatment of tin ores from mines in Cornwall and Devon. Cornish interests, which were receiving £12 10s. to £15 10s. per long ton for their white arsenic in 1936, lowered their price to £12 per ton in March 1937.

Lunevale Products, Ltd., Lancaster, has obtained a patent on a modified process for the production of a substantially dry sodium arsenite, for which are claimed moisture-resisting properties.⁵

U. S. S. R. (Russia).—Arsenic is reported to be produced from deposits in the Southern Urals, Tadzhikistan, and near the Angara River in Siberia. A new arsenic plant is also under construction in Upper Svanetia.

BISMUTH

Domestic production of bismuth in 1936 probably increased substantially, but statistical details are not available. As imports of the metal also increased, it is reasonable to assume that consumption was much greater. Pharmaceutical compounds continue to be the principal consumers of bismuth, but the many useful alloys now available indicate that this field offers the best opportunity for expanding the use of bismuth. Prices were maintained at \$1 per pound in New York throughout 1936.

Outside the United States, substantial gains in output were reported during 1936 by Canada and Peru, but Mexican output declined.

PRODUCTION

Statistics on the domestic production of bismuth are not available. Since 1935 the three major producers of bismuth in the United States have been the American Smelting & Refining Co., United States

⁴ Robak, C. A., *Progress in Research on Arsenic Fungicides Shown: Ind. and Eng. Chem. (News Ed.)*, vol. 14, no. 15, Aug. 10, 1936, pp. 298-299.

⁵ Chemical Industries, February 1936, vol. 38, no. 2, p. 163.

Smelting, Refining & Mining Co., and Anaconda Copper Mining Co. The American Bismuth Mines are also reported to recover bismuth at its property 10 miles northwest of Tyrone, N. Mex.⁶ Besides these domestic producers, the Cerro de Pasco Copper Corporation and the American Metal Co. are important distributors of bismuth in this country.

Some bismuth is recovered from imported lead bullion, alloys, ores, and residues coming principally from Peru, Mexico, and Canada.

CONSUMPTION

Approximately 75 percent of the world production of bismuth is used in the manufacture of pharmaceutical compounds, which require a product better than 99.99 percent pure. These are used chiefly in indigestion remedies, astringents, and toilet powders and in treating wounds. Next in importance is the use of the metal in the production of low-melting-point and nonshrinking alloys. Low-melting alloys are used in making safety plugs for boilers and compressed-gas storage cylinders, automatic sprinkler heads, fire-door releases, dental models, and low-melting solders. Fusible bismuth alloys usually include lead, tin, cadmium, mercury, or antimony. The ternary eutectic of bismuth, lead, and tin melts at 205° F., and the binary eutectic of bismuth and lead melts at 257° F. An almost endless series of alloys with melting points between warm water and the melting point of lead may be obtained by modification of the composition of the alloys.

A matrix alloy of bismuth, lead, tin, and antimony is marketed for use in mounting punch and die parts and to anchor parts accurately and permanently in machine tools, in molds for pressing cold plastics, and in a large number of other applications. This alloy melts at 248° F. and expands on cooling. A low-temperature-melting metal (160° F.) consisting of bismuth, lead, tin, and cadmium has been developed for bending tubing and metal molding and for joining the ends of quartz rods and tubes. A lead-bismuth alloy that melts at 255° F. and does not expand or contract on solidifying is used in the foundry to duplicate wood patterns, in making low-melting and fusible alloys, and as a fusible metal for safety purposes. Small amounts of bismuth are also consumed in the manufacture of special instruments, in iron castings, in aluminum alloys, in the production of X-ray-proof rubber goods, and in special brake linings.⁷ Minor amounts of bismuth compounds are used in porcelain painting, enameling, and optical-glass manufacture.

PRICES

According to the Engineering and Mining Journal Metal and Mineral Markets, the New York price for bismuth metal remained unchanged at \$1 per pound in ton lots throughout 1936. London quotations remained at 4s. per pound.

FOREIGN TRADE

Imports of bismuth metal during 1936 were 11 percent greater than in 1935. Additional quantities are imported in intermediate metallurgical products, statistical data for which are not available. Exports of bismuth metal are not recorded but normally are unimportant.

Bismuth and "compounds, mixtures, and salts of bismuth" imported for consumption in the United States, 1932-36

Year	Bismuth		Compounds, mixtures, and salts of bismuth	
	Pounds	Value	Pounds	Value
1932.....	28, 620	\$29, 295	3, 095	\$5, 283
1933.....	28, 530	28, 504	36	206
1934.....	19, 327	19, 927	305	1, 814
1935.....	102, 051	78, 061	871	4, 798
1936.....	113, 443	86, 722	564	4, 807

WORLD PRODUCTION

Official data on the total world output of bismuth are not available. The United States, Peru, Mexico, Canada, Spain, Germany, and Japan are the principal producing countries. Most of the world's bismuth is obtained as a byproduct from lead, copper, tin, silver, and gold ores.

On the North American Continent, besides the United States, Mexico and Canada are important bismuth producers. In Mexico ore containing 166 metric tons of bismuth was reported in 1936, compared with 214 tons in 1935. Canadian production totaled 165 metric tons compared with 6 tons in 1935. The Deloro Smelting & Refining Co., Deloro, Ontario, exports silver-lead-bismuth bullion obtained from the treatment of ores from Cobalt, and the Consolidated Mining & Smelting Co., Trail, British Columbia, produces metallic bismuth from lead-zinc ores.

Peru, Bolivia, and Argentina are the principal South American producers. The Cerro de Pasco Copper Corporation in Peru furnishes much of the world's bismuth, which is derived as a byproduct of lead smelting at its Oroya smelter. The Peruvian output increased from 151 metric tons in 1935 to 386 tons in 1936. The 1935 exports totaled 112 tons of metal of 99.9 percent purity. In Bolivia, bismuth is recovered as a byproduct of tin-silver mining. Production netted 64 metric tons in 1936. The high-grade bismuth mines of the Compagnie Aramayo de Mines en Bolivie at Tasna ceased operating after 1929, when Cerro de Pasco became a large factor in the bismuth industry.

In Europe, Spain, Germany, the United Kingdom, Sweden, France, and Rumania produce bismuth. The principal producer is Spain, with mines at Azuel and near Torrescampos in the Province of Cordoba. German bismuth is obtained as a byproduct from imported ores and from domestic ores coming from the Erzgebirge in Saxony. The United Kingdom has long marketed and refined bismuth. In Sweden the sulphide ores of Boliden carry bismuth. The Société des Mines et Usines de Salsigne in southern France produces a small amount of bismuth.

In Australia, Queensland and New South Wales produce most of the bismuth, usually found associated with gold ores. The Bismuth Products, Ltd., at Mount Biggenden, Queensland, produced 40,316 pounds of bismuth from 6,759 tons of ore in 1935 compared with 26,332 pounds of bismuth in 1934.

Japan and China produce most of Asia's bismuth output. Japanese production (54 metric tons in 1935) is chiefly a byproduct of copper and lead smelting.

The Union of South Africa produced 19 metric tons of bismuth in 1936. The altered pegmatite in the Steinkopf Native Reserve of Namaqualand is the principal source of supply.³

MAGNESIUM

By HERBERT A. FRANKE

SUMMARY OUTLINE

	Page		Page
Summary.....	721	Foreign trade.....	725
Production.....	721	Technologic developments.....	725
Consumption.....	722	World production.....	726
Prices.....	724		

Domestic production (sales) of metallic magnesium in 1936 declined 8 percent compared with 1935, but this decline probably was due to loss of foreign markets, recently an important factor in total sales, rather than to decreased consumption in the United States. Lack of data on the volume of exports of this metal prevents an accurate appraisal of domestic consumption, but increased activity in the various industries using magnesium suggests a substantial rise in its use in 1936. Consumption of magnesium as a deoxidizer in the metallurgical industry and as a component in aluminum and other alloys probably continued at a high rate. Outstanding in 1936, however, was the increased application of high-magnesium alloys as construction materials. Castings and extruded products led this advance. The quoted nominal price of magnesium at New York remained unchanged at 30 cents per pound.

The world magnesium industry made rapid strides in 1936. Several countries began producing for the first time, and others expanded their output and improved their processes. Germany remained by far the chief producer. Increased activity abroad was due largely to armament and self-sufficiency programs, although new commercial uses and improved business conditions also were important factors. In Europe as well as the United States the use of magnesium alloys in aircraft, transportation, and portable equipment is extensive and growing rapidly.

PRODUCTION

Since 1930 data on actual production have not been available, but the quantities sold annually have been reported. These include exports and amounts used by the manufacturer in other products.

The Dow Chemical Co. of Midland, Mich., continued to be the sole producer of magnesium in the United States in 1936. Sales of new metal in 1936 decreased 8 percent from 1935. Secondary magnesium has not yet become an important factor in the industry. Byproducts derived from the fabrication of magnesium products are cleaned and reused by the manufacturers, but there is no established scrap market.

Domestic primary magnesium sold or used, 1929-36

Year	Pounds	Value	Year	Pounds	Value
1929-----	908,351	\$512,313	1933-----	1,434,893	\$377,181
1930-----	559,631	268,864	1934-----	4,249,838	(¹)
1931-----	580,463	199,633	1935-----	4,241,218	(¹)
1932-----	791,699	228,653	1936-----	3,903,312	(¹)

¹ Bureau of Mines not at liberty to publish figures.

Commercial production of magnesium began in the United States in 1915. By 1917 there were five producers, but when Government war requirements for magnesium ceased the number of producers declined. Subsequently, the American Magnesium Corporation at Niagara Falls, N. Y., and the Dow Chemical Co. at Midland, Mich., were the only producers. Since May 1927 Dow Chemical Co. has furnished all of the domestic output. The American Magnesium Corporation moved its fabrication equipment to Cleveland, Ohio, in July 1928, where it continues to manufacture magnesium products.

Magnesite was used formerly as a raw material in making ingot magnesium, but now natural brine pumped from wells 1,200 to 1,400 feet deep is used. Magnesium is only one of many products made from the brine, which contains approximately 14 percent NaCl, 9 percent CaCl_2 , 3 percent MgCl_2 , and 0.15 percent bromine. One hundred pounds of brine contains approximately three-fourths pound of magnesium. The bromine and sodium and calcium salts are removed by evaporation, filtration, and fractional crystallization, with addition of chlorine during the process. The purified magnesium chloride solution is concentrated further by crystallization. The crystals are melted in their water of crystallization, the fused mass flaked and then air-dried until an almost anhydrous MgCl_2 is produced. This is electrolyzed in a sodium chloride bath. The process is continuous, and the metal, which is of high purity, is periodically dipped from the rectangular cast-steel pots in which electrolysis occurs and cast into ingots of various sizes. The methods used by the Dow Chemical Co., as described by Dr. John A. Gann in 1930 and 1932, are still in general practice, except that the final drying of the MgCl_2 in an atmosphere of hot hydrochloric-acid gas has been abandoned.¹ Electrolytic cells are now operated at 50,000-ampere capacity.

CONSUMPTION

Virtually all magnesium consumed in the United States is of domestic origin. Imports are insignificant, but exports are reported to be large, although exact data are not available. Owing to the lack of export data it is impossible to determine the total consumption of magnesium in this country.

Magnesium was first used in pyrotechnics, but since the domestic industry began it has found many other applications. The principal uses of the metal at present are as a deoxidizer in the metallurgical treatment of other metals and in the manufacture of alloys.

Owing to its affinity for oxygen and nitrogen, magnesium is an excellent deoxidizer or scavenger for such metals as brass, bronze,

¹ Gann, John A., *The Magnesium Industry: Ind. and Eng. Chem.*, vol. 22, 1930, p. 694; *Magnesium: Min. and Met.*, vol. 13, 1932, pp. 179-183.

nickel, and nickel-silver. Added to the melts of these metals it forms a lightweight magnesium oxide which rises to the surface and can be skimmed off. The amount of magnesium added usually ranges from 0.05 to 0.2 percent of the weight of the metal treated, but the total amount used accounts for an appreciable part of the magnesium consumed.

The use of magnesium in alloys is expanding more rapidly than other uses. The high-strength aluminum alloys containing 0.2 to 10.0 percent magnesium were the first to be used extensively, but in recent years alloys with high magnesium content have been increasing in importance. The combination of high strength and lightness with good machinability has contributed to the expanding market for magnesium alloys in the aircraft and transportation industries. On a volume basis, 1 pound of magnesium equals 1½ pounds of aluminum and about 5 pounds of copper. Data on the production of alloys with low magnesium content are not available, but domestic fabricators have reported sales and use of high magnesium alloys to the Bureau of Mines for several years.

Magnesium products (other than ingot and stick magnesium) manufactured in the United States and sold or used by the companies manufacturing the products, 1934-36

[This table includes only the products made from magnesium or alloys containing high percentages of magnesium. It does not include the large quantity of metal used as a deoxidizer and in alloys with low magnesium content]

¹ Bureau of Mines not at liberty to publish figures.

² Some products formerly classified as "Wire and ribbon" are included under "Structural shapes, rods, and tubing" in 1936.

³ In 1934, small quantity of miscellaneous, unspecified, nonstructural products included under "Other structural"; separate figures not available.

⁴ In 1934, small unspecified quantity of miscellaneous nonstructural products included under "Total structural products."

⁵ In 1934-35, inclusive, minor quantities of shavings included under "Powder"; separate figures not available.

The quantity of structural products sold or used in the United States in 1936 increased 70 percent over 1935, whereas sales of nonstructural products decreased 34 percent; sales of alloy ingot increased 184 percent. There were 10 manufacturers of magnesium products in 1936.

Among the structural products the greatest improvement was shown in castings and extruded products, such as structural shapes,

rods, and tubings. The quantity of castings produced in 1936 increased 111 percent over 1935. Output of both die and sand castings increased in 1936. The Hoover Co. completed a new plant for the production, machining, and finishing of magnesium-alloy die castings for use in vacuum cleaners. Approximately 5,000 castings are produced daily. Die castings were also adopted in such devices as automatic hammers, binoculars, and radio-transmitting cases.

Larger quantities of sand castings were used during 1936 in aircraft-engine parts, such as crankcases, oil pans, blower sections, rear accessory cases, oil pumps, and cam-shaft bearings and in other airplane equipment, such as landing wheels, cockpit fittings, and automatic-pilot parts. More sand castings were used for needle bars and other moving parts in textile machinery, bread slicing and wrapping equipment, ventilating fans, safety blocks used in die presswork, foundry flasks, patterns, core boxes, match plates, motion-picture cameras, addressing machines, and welding equipment. New uses developed for sand castings included parts for shoemaking, printing, and

FIGURE 41.—Trends in quoted price and production of magnesium in the United States, 1915-36.

cigarette-making machinery, duplicators, scales, spray guns, mimeographs, and musical instruments of the percussion type.

The value of magnesium castings averaged \$1.19 per pound in 1936 compared with \$1.57 in 1935.

During 1936 the manufacture of magnesium extruded products increased 45 percent over 1935. Round, square, hexagonal, and rectangular bars, structural shapes, and moldings of complex shapes were employed for stressed members of rapidly moving equipment, for coach-seat parts, and as screw-machine stock.

In the process of development are uses for magnesium in the making of welded oil tanks for aircraft, etching plates for the printing industry, parts of military utility carts and gun carriages, magnesium-alloy forgings for use as aircraft propellers, and magnesium castings, extrusions and rolled sheets in bus and coach manufacture.

The high-magnesium alloys are known in the world trade by various names, such as Magnalium, Dowmetal, Elektron, AM Alloys, Bohnalite X, Hydronalium, and Maxium.

PRICES

According to the Engineering and Mining Journal Metal and Mineral Markets the nominal New York price for 99.8-percent ingot magnesium remained unchanged at 30 cents per pound, carload lots,

throughout 1936. Quotations for less than carload lots, 100 pounds or more, were 32 cents per pound, with a premium of 5 cents a pound over ingot price for specified stick sizes ($\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$, 1, and 2 pounds each). The four notched ingots commonly furnished are 4 by 4 by 28 inches and weigh approximately 17 pounds. Alloy ingot is normally quoted at 3 cents per pound more than pure magnesium ingot. London quotations for magnesium ingot and stick remained at 1s. 6d. to 1s. 7d. per pound during 1936.

FOREIGN TRADE

Imports of magnesium are unimportant. Imports of powder were 1,108 pounds valued at \$1,453 in 1936, compared with 882 pounds valued at \$1,252 in 1935. Imports of sheets, tubing, ribbons, wire, and other magnesium products totaled 18 pounds valued at \$26 in 1936 compared with 2 pounds valued at \$40 in 1935. Exports of magnesium, mainly as ingot, are not separately recorded but have been relatively large since 1933. Reports state that 2,000,000 pounds of Dowmetal were sold to Europe during the first 6 months of 1935.

TECHNOLOGIC DEVELOPMENTS

An improved process for the manufacture of magnesium is said to have been developed in Austria.² Magnesium oxide, obtained by calcining magnesite or dolomite, is reduced by carbon in an electric furnace at a temperature of about 2,000° C., which is well above the boiling point of magnesium metal. The metallic vapor, which leaves the furnace mixed with carbon gases, is filtered from accompanying dust and rapidly cooled to 200° C. The cooled product, comprising a mixture of magnesium metal, oxide dust, and soot, is heated to 800° to 1,000° C. in an electric furnace under partial vacuum (20 to 100 mm mercury) in the presence of hydrogen or methane. Here the magnesium is again vaporized and cooled to the liquefying but not to the solidifying point. The liquefied metal falls in drops into a bath of hydrocarbon oil of high boiling point. The oil causes the drops to coalesce into granules 10 to 20 mm in diameter and at the same time separates any dust, so that the metal isolated is about 99.97 percent pure. The metal and dust can be separated easily and independently from the oil. Aluminum or silicon, or a mixture of the two, can be used as the reducing agent instead of carbon, thereby eliminating the formation of gases so that only magnesium vapor escapes from the furnace. This new method produces a metal free from injurious salts. It is said that producing units of 5,000 to 10,000 kw.-hr. capacity are possible with this process.

Much progress has been made in developing new magnesium alloys and they have been well described in recent literature.³

The founding of magnesium alloys is the subject of a recent paper by Gann and Brooks.⁴

⁴ Gann, John A., and Brooks, M. E., Founding Magnesium Alloys: Paper presented at 1935 Convention of Am. Foundrymen's Assoc., Toronto, Canada, 24 pp.

Magnesium-alloy die castings have been improved as a result of technical progress. The old gooseneck machine has been supplanted by modern, hydraulically operated, plunger-type machines similar to those used in the brass industry.

A new alloy has been developed that can be heat-treated after it has been shaped by extrusion and press forming. It has improved yield strength and good corrosion resistance.

Chemical treatment of magnesium alloys has proved the most satisfactory method for increasing corrosion resistance under saline conditions. The most widely used treatment consists of a dip in a nitric acid-sodium dichromate solution.⁵ This chrome-pickle treatment when properly applied protects the alloy well from corrosion and makes it an excellent paint base, but as the treatment reduces the cross section of the metal it cannot be used on dimension-machined surfaces. The alkaline chromate treatment⁶ can be used on such surfaces but gives inferior protection against corrosion. The National Bureau of Standards reports the perfection of a process combining the desirable features of both methods. This process consists of cleaning the metal in an electrolytic bath of sodium carbonate and trisodium phosphate then treating it in an anodic bath containing 10 percent sodium dichromate and 2 to 5 percent monosodium phosphate.⁷

The United States Bureau of Mines is investigating the production of magnesium from magnesites of the Northwest. A series of flotation tests is in progress on the beneficiation of crude and calcined magnesite. Separation of magnesia and silica in the calcined product is being attempted by flotation. After a study of the literature it has been concluded that two methods offer the best possibilities for profitable extraction of magnesium from magnesite ores: Chlorination of technically pure MgO by heating it with carbon and chlorine, followed by electrolysis of the fused chloride; and direct electrothermic reduction of calcined magnesite by carbon and purification of the product by redistillation. Experiments are being conducted with the latter method.

WORLD PRODUCTION

The production and fabrication of magnesium have advanced rapidly during the past few years, but published details of processes, output, and general progress are not available. Germany continues to retain the title of the world's chief producer of metallic magnesium and its output probably surpasses that of the rest of the world combined. Most of the metal has been produced by electrolysis of magnesium chloride, about two-thirds of which is derived from magnesite and dolomite, while the rest comes from brines and carnallite. World magnesium production has been estimated at 30,000 to 35,000 metric tons in 1934 and about 50,000 tons in 1935. A more conservative estimate would probably be about 9,000 metric tons in 1934; 11,000, in 1935; and 15,000, in 1936. The world producers in apparent order of importance are Germany, United States, France, Switzerland, United Kingdom, Japan, U. S. S. R. (Russia), and Austria.

Australia.—Further negotiations for the production of magnesium are contemplated by the Australia Magnesium Co. of Hobart, Tasmania, which carried on some experimental work with dolomite about 1935.

Austria.—The Österreichisch-Amerikanische Magnesit A. G. (Austro-American Magnesite Co.) has an experimental plant for the production of magnesium at Radenthein, Carinthia, about 6 miles south of its magnesite mines. This pilot plant, with a daily capacity of 770 pounds has been operated intermittently since 1930. The process is described in this chapter under Technologic Developments. The construction of a commercial plant is anticipated.

Although official statistics are not available it is reliably reported that 2,697 kilos (5,933 pounds) of magnesium were imported in 1936 from German ports, Switzerland, and the United Kingdom. Approximately 10,000 metric tons of crude magnesite are shipped annually from the Zillerthal mine to the I. G. Farbenindustrie plant at Bitterfeld, Germany, to be converted into magnesium. This ore has less than 1½ percent of iron, and 4 tons of the crude magnesite are said to produce 1 ton of metallic magnesium. Austria supplies magnesite to many other countries for the production of magnesium.

Canada.—No magnesium has been produced in Canada since the World War, when the Shawinigan Electro-Metals Co., Ltd., was a producer at Shawinigan Falls, Quebec. The company no longer exists, and the plant has been dismantled.

France.—The principal producers of magnesium are Compagnie Alais, Forges et Camarque (Péchiney) at Saint-Auban (Basses Alpes) and Société d'Electrochimie, d'Electrometallurgie et des Acieries Electriques d'Ugine at Jarrie (Isère). The Société Générale du Magnésium is the exclusive fabricating and sales agency for these two firms. Smaller quantities of the metal are produced by the Société Bozel-Maletra at Villard (Haute Savoie) and other companies.

The raw materials utilized in magnesium production are magnesite, carnallite, and dolomite. Carnallite and dolomite are found in abundance in France, but magnesite must be imported from Greece and the Tyrol, Austria.

According to unofficial figures the French magnesium output increased from about 100 metric tons in 1932 to more than 1,300 in 1936. Consumption, with which production has kept pace, was estimated at 80 metric tons in 1932, 200 in 1933, 300 in 1934, 700 in 1935, and 1,200 in 1936. Imports of magnesium are said to have totaled 61 metric tons in 1931, 24 in 1932, 7 in 1933, 5 in 1934, 20 in 1935, and 19 in 1936, most of which came from Germany, Switzerland, United Kingdom, and the United States. Magnesium exports are reported as 6 metric tons in 1931, 1 each in 1932 and 1933, 20 in 1934, and 80 each in 1935 and 1936 and are consigned to Central Europe, U. S. S. R. (Russia), and the United Kingdom.

Germany.—The Bitterfeld plant of I. G. Farbenindustrie is the largest producer of metallic magnesium in the world. The other German producer, Wintershall A. G., Heringen-Wintershall, began operations in 1934 and uses carnallite ($\text{KMgCl}_3 \cdot 6\text{H}_2\text{O}$) as the raw material; its 1935 output was 4 to 5 tons per day.

The Bitterfeld plant is said to have used carnallite as the raw material until 1932, when it changed to imported magnesite. Recent reports, however, indicate that the I. G. Farbenindustrie is gradually

reverting to carnallite and dolomite, both domestic materials.⁸ The production of magnesium from carnallite is a discontinuous process and apparently comprises fractional crystallization of magnesium chloride from the natural salt, drying by hydrochloric-acid gas or chlorine, and electrolysis.⁹ The magnesia process consists of the chlorination of dead-burned magnesite at a high temperature in the presence of special grades of carbon. The resultant $MgCl_2$ is decomposed electrolytically to produce magnesium and chlorine; the latter is used again in the exothermic reaction,

It is stated that 18 tons of carnallite yields 10 tons of calcined product which in turn yields 1 ton of magnesium. Dolomite also is used as a raw material at Bitterfeld; its use was made possible by the invention of a method for distilling the crude metal obtained by thermal reduction of magnesia with coal. This method is probably similar to that used in Austria.

Official statistics on German magnesium production and foreign trade have never been revealed. The annual output was estimated at 2,000 metric tons prior to 1933, but later estimates range from 25,000 metric tons in 1934 to 35,000 in 1935. These figures are probably too high, and more conservative estimates indicate that the annual output in recent years has not exceeded 8,000 tons. Domestic output of magnesite increased from 5,700 metric tons in 1933 to 13,800 in 1935, and imports increased from 53,388 tons in 1933 to an estimated 150,000 in 1936. The amount of magnesite consumed by the magnesium industry is not known. It is believed that exports of magnesium and its alloys are considerable, but probably they have not exceeded 3,000 tons annually during the last 5 years.

Italy.—The Montecatini group has obtained authorization from the Government to construct a plant for the production of magnesium at Porto Marghera. Initial plans are to produce 150 tons a year, using magnesite. The Minerals Chemicals of Sulcis in Sardinia, controlled by Isotta Fraschini, is reported recently to have begun the production of magnesium. Presumably magnesium-bearing brines, obtained from the evaporating ponds for sea salt at Cagliari, are used as the raw material. Italy has dolomite in Tuscany and the Dolomites, and magnesite in Sardinia.

Japan.—The only commercial producer of magnesium in Japan is the Nichiman Magnesium Kabushiki Kaisha (Japan-Manchukuo Magnesium Co., Ltd.), which merged with the Riken Magnesium K. K., the South Manchurian Railway and other interests in October 1933, acquiring the 150-ton magnesium plant at Naoetsu in Niigata Prefecture. Besides this plant, which uses sea water bittern, it owns the recently constructed 700-ton capacity plant at Ube in Yamaguchi Prefecture. Two processes are used at this plant, and the chlorine gas, recovered from the electrolysis of magnesium chloride derived from sea water bittern by dehydration in one process, is utilized in the second electrolytic process employing calcined magnesite. Expansion of the Ube magnesium plant to 1,000-ton capacity by the end of 1937 will permit closing the Naoetsu works. One metric ton of magnesium requires from 17 to 20 tons of solid bittern and about 50,000 kilowatts of power.

⁸ U. S. Bureau of Mines, Mineral Trade Notes: Vol. 4, no. 3, Mar. 20, 1937, pp. 8-10.

⁹ L'Industrie Chimique, (French), The Fabrication of Magnesium and of Magnesia: 1936, p. 802.

The Nippon Magnesium Kinzoku K. K. (Japan Magnesium Metal Co., Ltd.) built a magnesium plant in Konan, Korea, in 1934, using the thermal reduction process, with near-by magnesite as the raw material. This plant, still in the experimental stage, plans an annual capacity of 2,000 metric tons. The Asahi Denka Kogyo K. K. (Asahi Electro-Chemical Industry Co., Ltd.) is experimenting with its own process of electrolyzing calcined magnesite and contemplates a 350-ton annual capacity. The Nippon Soda K. K. (Japan Soda Co., Ltd.) proposes an annual production of 300 tons by the electrolysis of calcined magnesite.

Japanese magnesium production was 3,219 kilograms in 1931, 24,018 in 1932, 104,812 in 1933, and 140,808 in 1934. All official data terminated after 1934, but output is estimated at 350,000 kilograms in 1935 and 650,000 in 1936. Japanese imports were 8,996 kilograms in 1930, 8,328 in 1931, 19,328 in 1932, 25,515 in 1933, and 617 in 1934, principally from Germany. There were probably no imports in 1935 and 1936, and Japan began exporting magnesium in 1934, shipping 3,502 kilograms to the United Kingdom.

Norway.—The Norwegian Salt Works near Bergen ceased production of magnesium some years ago.

Switzerland.—Magnesium has been produced from magnesite and dolomite by the S. A. pour la Fabrication du Magnésium at Martigny since 1926. Magnesite is imported chiefly from Germany, the Netherlands, and Austria. Domestic dolomite is available in the Cantons of Tessin and Vaud. Estimated output for 1936 is about 700 metric tons.

U. S. S. R. (Russia).—By the end of 1936 Russia had 15 furnaces in operation for the production of magnesium from carnallite at the Solikamsk works in the Ural Mountains. The recently completed Dnepr plant at Neproges uses magnesium chloride obtained from the Saki Lakes, Crimean Peninsula. The Leningrad Experimental Magnesium Metal Plant at Leningrad is investigating production of the metal from magnesite and dolomite.

United Kingdom.—Magnesium Metal & Alloys, Ltd., Rainham, Essex, began to produce magnesium in April 1935 and is now extending its plant to increase output. The company is under the control of Murex, Ltd., which is purchasing the interest of Messrs. Johnson, Matthey & Co. The former alinement of interests that included this concern disbanded in October 1936.¹⁰ Magnesium Elektron, Ltd., at Clifton Junction near Manchester, formed early in 1936 by F. A. Hughes & Co., London, holds the magnesium production and fabrication of patents of I. G. Farbenindustrie. Production was begun early in 1937, and an initial output of 150 tons monthly was planned. Both companies use magnesite imported chiefly from Austria and Greece. The Imperial Magnesium Corporation, Ltd., owned jointly by the British Aluminium Co., Ltd., and the Imperial Smelting Corporation, is now erecting a plant at Swansea, England, to produce magnesium. It has acquired a license to use the Austrian thermal reduction process and plans a plant with a final capacity of 7,000 tons annually.

Other countries.—Production of metallic magnesium has been proposed in the Netherlands and Poland.

ANTIMONY

Apparent consumption of primary antimony in the United States in 1936, reflecting the general improvement in business, increased 80 percent over that of 1935 and was the largest recorded since 1929. Imports were 85 percent higher and continued to be the chief source of supply. Domestic mines produced 29 percent more antimony than in 1935, but contributed only 10 percent of the total consumption. Price fluctuations were not so pronounced as in 1935. The average New York quotation for Chinese brands was lower—12.97 cents per pound compared with 14.08 cents in 1935. The average for domestic brands was 12.25 cents in 1936 and 13.62 cents in 1935. Late in 1936 prices of nearly all metals moved upward in response to an unusual demand that developed in Europe and the United States. Antimony prices shared in this movement, and by March 1937 the New York quotation had exceeded 16 cents, notwithstanding the fact that the leading producer in the United States previously had announced its desire to keep the maximum price below 14 cents and the average price at 12 cents.

World production increased 15 percent despite a decline in output in China, whose contribution to the world total dropped from 71 percent in 1929 to 53 percent in 1936. Mexico and South America made notable advances in production in 1936.

The Chinese industry was affected adversely by political conditions. Apparently the first year of control of the industry by the National Government was unsuccessful, as reports indicate considerable friction between the Antimony Administration, dealers, and producers. During the latter part of 1936 dealers at Changsha engaged in a speculative orgy, which prompted the Administration early in 1937

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

to adopt drastic measures of control in an endeavor to stabilize the market. Producers retaliated by withholding supplies, and reports for April indicated that shipments of metal from Changsha had ceased.

¹ Revised figures.

² According to American Metal Market.

³ Chinese grade. American grade was quoted at 13.62 cents a pound for 1935 and 12.25 cents for 1936.

FIGURE 42.—Trends in world production, United States imports, and New York price of antimony, 1910-36.

The strategic position of the United States with respect to antimony recently underwent an important change. In 1929 about 70 percent of all antimony imported came from China, whereas in 1936 less than 10 percent was of Chinese origin and about 90 percent came from Mexico and South America. Coincident with this shift in source was a change in the nature of the products imported. About 70 percent of the 1929 shipments was regulus and 11 percent was ore, whereas in 1936, 76 percent was ore and only 8 percent was metal. This change was made possible by an increase in smelting capacity in the United States, which enlarged the market for Mexican, South

American, and, to a smaller extent, domestic ores. The domestic industry can now supply large tonnages of metal and oxides to the trade.

From a military viewpoint, dependence on American sources of supply is preferable to dependence on Asiatic sources, because in an emergency the former could be maintained more easily than the latter. One important factor, however, which has not been investigated thoroughly, is the adequacy of antimony reserves in North and South America. This is important, as it involves the permanence of the present domestic industry. Obviously, the Chinese, with their abundant and rich deposits, will not permit the loss of the world's largest market without a struggle.

DOMESTIC PRODUCTION

Mine output.—Antimony mined in the United States is derived from both antimony ores and lead ores, the latter being the more important source. Byproduct antimonial drosses obtained in refining lead bullion are used in the manufacture of antimonial lead, other alloys, and various antimony compounds such as oxides and sulphides. In 1936, 1,434 tons of antimony derived from domestic lead and antimony ores were recovered in antimonial lead; data on the quantity recovered in other alloys and compounds are not available.

The antimony content of antimony ores and concentrates produced in 1936 was the highest recorded since 1916. Of the 755 tons reported, 729 were contributed by the Yellow Pine Co. in Valley County, Idaho. The remainder was supplied by three small producers in Nevada and one in Washington. The Arkansas Antimony Corporation, De Queen, Ark., began mining early in 1937. No production was reported from Alaska in 1936; but Morris P. Kirk & Son, Inc., an affiliate of the National Lead Co., acquired the Stampede mine in the Kantishna district and began shipping ore early in 1937.

Mine production of antimony ores and concentrates in the United States, 1932-36, in short tons

Year	Ore and concentrates	Antimony content	Year	Ore and concentrates	Antimony content
1932.....	900	419	1935.....	1 3, 616	1 559
1933.....	1, 133	587	1936.....	3, 867	755
1934.....	897	404			

¹ Revised figures.

Smelter output.—The only active primary antimony smelter in the United States is that of the Texas Mining & Smelting Co. at Laredo, Tex., which treats largely Mexican ores. The plant, which produces antimony oxide in addition to metal, was put into operation at the beginning of 1931. Its annual output has been as follows:

Antimony produced by the Texas Mining & Smelting Co., 1931-36, in short tons

Year	Antimony metal	Antimony oxide	Year	Antimony metal	Antimony oxide
1931.....	2, 201	577	1934.....	1, 797	517
1932.....	1, 775	100	1935.....	2, 134	1, 007
1933.....	1, 204	68	1936.....	3, 451	1, 423

Except for 1933 and 1934, when one other company was producing, the foregoing statement of antimony-metal production represents the entire domestic output since 1929. Additions to the Laredo smelter, completed in 1937, have increased the monthly capacity to 900 tons. This may be varied, according to demand, between 900 tons of metal with no oxide and 600 tons of metal with 300 tons of oxide.

Details of antimonial lead production at primary lead refineries are shown in the accompanying table. These represent only part of the total antimonial lead output, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

Antimonial lead produced at primary lead refineries, 1929-36

Year	Production (short tons)	Antimony content				
		From do- mestic ores (short tons)	From for- eign ores ¹ (short tons)	From scrap (short tons)	Total	
					Short tons	Percent
1929.....	43, 244	2, 311	741	1, 883	4, 935	11. 9
1930.....	24, 797	1, 302	383	1, 282	2, 967	12. 0
1931.....	21, 842	768	196	1, 474	2, 438	11. 2
1932.....	21, 024	878	207	1, 410	2, 495	11. 9
1933.....	17, 805	870	57	793	1, 720	9. 7
1934.....	16, 607	1, 657	18	588	2, 263	13. 6
1935.....	16, 384	1, 110	26	593	1, 729	10. 6
1936.....	23, 230	1, 434	37	691	2, 162	9. 3

¹ Includes lead ores, antimony ores, and metallic antimony.

Secondary production.—The following table shows the total amount of secondary antimony recovered in the United States from scrap. Additional information is given in the chapter entitled "Secondary Metals."

Secondary antimony recovered from old alloys, scrap, and dross, in the United States, 1932-36

Year	Short tons	Value ¹	Year	Short tons	Value ¹
1932.....	6, 450	\$725, 000	1935.....	9, 600	\$2, 703, 400
1933.....	7, 400	963, 500	1936.....	9, 900	2, 568, 100
1934.....	7, 550	1, 346, 900			

¹ Values calculated at average yearly price for ordinary brands of antimony as published by the American Metal Market.

DOMESTIC CONSUMPTION

Precise data on the consumption of primary antimony in the United States are not available owing to lack of information on dealer and consumer stocks. An approximate idea of the trend of consumption, however, can be obtained from the following table, which shows the annual supply available for consumption.

Primary antimony available for consumption in the United States, 1929-36, in short tons

	1929	1930	1931	1932	1933	1934	1935	1936
Domestic antimony recovered in antimonial lead.....	2,311	1,302	768	878	870	1,657	1,110	1,434
Imports for consumption (antimony content):
